CASE 2—History—A Negro boy aged 4 months was admitted to Parkland Hospital on June 11, 1944 because of fever and deepened respirations. The child was well until about three days before admission when he developed a mild cold. One day before admission the mother thought the child had fever and she gave it half of an acetylsalicylic acid tablet (0.17 Gm) every four hours for four doses and also gave mild protein silver in castor oil as nose drops. The child seemed to be about the same until approximately twelve hours before admission when the respirations were noted to be very deep and rapid. This continued until admission at 5:30 a. m. The baby had had no diarrhea, cough or other symptoms.

The child was a full term delivery, with uncomplicated labor and had had no previous illnesses or immunizations.

Physical examination showed that he was well developed and well nourished. His respirations were very deep and rapid and he was apparently unconscious. The temperature was 102 F, pulse rate 120, respiratory rate 45. The head was normal in size but there was pronounced craniotabes. The anterior fontanel was soft. The ear drums were mildly injected. The mouth was negative but the throat was slightly generally reddened. No membrane was present. Respiration was heaving in type

A catheterized urine specimen showed acetone 4 plus, sugar negative. An x-ray examination of the chest revealed patchy areas of increased density throughout both lung fields.

With air hunger type of respirations and 4 plus acetone, the child was thought to be in a state of acidosis, 220 cc of lactate-isotonic solution of three chlorides was given intravenously and 250 cc subcutaneously. The temperature rose to 106 F, and half of an acetylsalicylic acid tablet (0.17 Gm) was given on

Fig. 4—Microscopic appearance of lung in case 1. There are pronounced recent hemorrhage and edema in the alveoli and acute hyperemia in the alveolar capillaries. Magnification 200 diameters.

Fig. 3 (case 1)—Microscopic appearance of a hemorrhagic lesion in the white substance of the cerebellum. Early encephalomalacia is present. Magnification 200 diameters.

but there was no chest retraction. The breath sounds were harsh, but no rales were present. The heart was normal in size to percussion. No murmurs were heard. There were beaded prominences along all the costochondral junctions. The abdomen was normal and the genitalia were normal. The skin was hot to touch around the head and trunk, while the extremities were cold. The extremities were relaxed and the reflexes depressed.

two occasions and also cool sponges. Sulfathiazole was administered, 0.5 Gm as the initial dose and 0.25 Gm every four hours. At 11 a. m., five and one-half hours after admission the child began having severe generalized convulsions, with which respirations became very poor. A lumbar puncture revealed, at this time, clear fluid, with no increase of pressure. Sodium phenobarbital 0.23 Gm was given slowly, intravenously until the convulsions were quieted. Oxygen was given by inhalation. The respirations became very slow, 6 to 10 per minute in spite of nikethamide, caffeine and epinephrine. Six hours later however, the child seemed to be improved, with regular respirations and only slight cyanosis. However, a few minutes later respirations dropped to 4 to 6 per minute and about one hour later the child died from respiratory failure twelve hours after admission.

Autopsy—This was performed two hours after death. The body weighed 14 pounds 10 ounces (6.6 Kg). Pronounced craniotabes and beading of the costochondral junctions of the ribs were noted to be present.

The trachea and main bronchi contained a small quantity of a thick greenish fluid resembling stomach contents. The right lung weighed 35 Gm and the upper lobe was dark purple, firm and airless. It exuded bloody fluid on pressure. The middle lobe was air containing and the lower lobe was mottled by collapsed blue, dry, airless areas. The left lung weighed 25 Gm and on section revealed diffusely red but air containing parenchyma. The bronchi of this lung contained a small amount of greenish mucoid fluid apparently stomach contents.

The liver weighed 250 Gm and appeared normal. The heart, thymus, gallbladder, spleen, pancreas, adrenals, kidneys, urinary bladder, prostate, testicles and epididymides, gastrointestinal tract and neck organs were normal.

The mesenteric lymph nodes seemed to be enlarged, varying from 0.5 to 1.5 cm in size.

The meninges were clear. Externally and on section through out the brain many dilated small vessels were seen. Only in

the hypothalamus could additional changes be seen with the naked eye. Here there were numerous very tiny pinpoint hemorrhages in the brain substance.

Microscopic Examination—Sections of the brain revealed very pronounced acute hyperemia everywhere in the brain substance and in the leptomeninges. There were noted numerous small recent, perivascular and interstitial hemorrhages in a section of the hypothalamus (fig 5) a few were also noted in the medulla just underlying the floor of the fourth ventricle and one such small hemorrhage was present in the medulla of the cerebellum. In the brain tissue adjacent to some of these hemorrhages there was slight myelin degeneration.

A section of the upper lobe of the right lung revealed pronounced acute hyperemia, edema fluid of high protein content and extensive diffuse, recent, intra-alveolar hemorrhage (fig 6). There was no inflammatory reaction. Elsewhere in the lung sections showed hyperemia, slight edema, small alveolar hemorrhages and focal atelectasis. The alveoli of most sections contained a greenish granular precipitated material.

In a section of heart a small epicardial petechial hemorrhage was found.

The liver was found to be the seat of fatty degeneration of advanced degree. There was hyperplasia of the splenic pulp and also slight lymphoid hyperplasia of a mesenteric lymph node.

There was acute hyperemia in the adrenal medulla, in the kidneys and in the large and small intestines.

Sections of the stomach, thymus, larynx, tongue, tonsil, thyroid, parathyroid, esophagus, gallbladder, testicle, epididymis and prostate were all essentially normal.

Bacteriologic Examination—Cultures of the upper lobe of the right lung and of splenic pulp were negative.

The main pathologic diagnoses were petechial hemorrhages in the hypothalamus, medulla and cerebellum, extensive hemorrhage in the right lung, petechial hemorrhage of the epicardium.

Fig 5 (case 2)—Microscopic section of region of hypothalamus showing recent petechiae. Magnification 200 diameters.

edema of the lungs, pronounced acute hyperemia of the brain, lungs, kidneys, adrenal medulla and large and small intestines, focal atelectasis of the lungs, aspiration of stomach contents and rickets.

The hyperpnea, hyperpyrexia and convulsions seemed to follow the comparatively large doses of acetylsalicylic acid, and the failure to demonstrate an inflammatory disease at autopsy makes it likely that these

toxic effects of salicylates were the cause of death. The dosage given is well above the toxic dose according to Barnett, Powers, Benward and Hartman.³

COMMENT

Previous reports of deaths due to salicylates have not emphasized hemorrhagic complications. Rapoport, Wing and Guest⁴ suggested that the hemorrhagic

Fig 6—Microscopic section of the lung in case 2. There is very evident hyperemia. The alveoli are filled with red blood cells and some edema fluid. Magnification 200 diameters.

tendency of some cases of rheumatic fever might be explained on the basis of the salicylate therapy. Stevenson⁵ reviewed the cases of poisoning from methyl salicylate and reported 3 cases of his own. There were 43 such cases. About half of the 13 cases in which autopsy was performed showed petechiae in the epicardium, and almost one third hemorrhages in pleura and lung. In none was a generalized hemorrhagic disease present, however.

Hypoprothrombinemia has been shown by Link and others⁶ to occur in rats which have received salicylates. These authors pointed out the similarity that exists between the salicylate radical and dicumarol, a strong hypoprothrombinemic agent (Meyer and Howard⁷ and Rapoport, Wing and Guest⁴ also produced hypoprothrombinemia in animals and in human beings with therapeutic doses of salicylates. It was shown that vitamin K prevented this hypoprothrombinemia so that it is likely that the hypoprothrombinemia is not due to the liver damage. However, Lutwak-Mann⁸ showed that the liver glycogen disappeared following salicylate

therapy. It is of some interest that in the 2 cases reported here degenerative changes were noted in the liver.

The severe generalized hyperemia in our 2 cases suggests the possibility of some capillary damage by the salicylates. The petechial hemorrhages can readily be explained on the basis of severe hyperemia with accompanying hypoprothrombinemia.

Tachypnea and hyperpnea in salicylate poisoning have been explained on the basis of fixed acid acidosis.⁹

In addition to the 2 cases reported here, Fashena and Walker have recently observed another case of nonfatal acute salicylate poisoning occurring in the course of treatment of rheumatic fever. This case was studied from the clinical and chemical standpoint.¹⁰

SUMMARY

Although severe toxic reactions following salicylate therapy are uncommon, the recent interest in more intensive forms of salicylate therapy renders the report of 2 cases of probable fatal salicylate poisoning of interest.

The outstanding findings at autopsy were hemorrhagic changes widespread over the body but particularly involving the brain, and severe widespread hyperemia. The explanation of these findings is probably a combination of capillary damage and hypoprothrombinemia produced by the salicylates.

It would seem that vitamin K is strongly indicated in all cases in which large doses of salicylates are administered.

THE USE OF THE SULFONAMIDES IN PYELONEPHRITIS IN PREGNANCY

E. GRANVILLE CRABTREE, M.D.
BOSTON

Introduction of the sulfonamide drugs into general use produced a radical alteration in the management of infections in pregnancy. The test of their effectiveness will rest on a survey of the condition of patients so treated after the lapse of five or more years after the illness with which the injury began. No adequate surveys have been made to date. A yardstick for comparison with similar cases treated by previous methods already exists. Such surveys are apt to follow soon after cessation of hostilities when sufficient man power becomes available for their prosecution. Meanwhile those in whose hands the care of such infections rests have attempted to determine essential requirements for maximum efficiency in the use of these drugs. This communication is limited to a statement of policy of the Boston Lying-in Hospital with some observations on the already obvious deficiencies of present practices and inadequacies of the drugs employed.

Optimism based on apparent cures of urinary infections in pregnancy following delivery which permitted uncured infections to persist and result in major degrees of damage to renal tissue and efferent channels in subsequent years has a corollary in the sulfonamide era when

prompt subsidence of symptoms and the production of a high percentage of cures tends to be accepted by those in charge as indicative of cure in all. This concept is still further magnified since bladder symptoms often remain mild or absent until retrogression of pregnancy changes has taken place at the end of weeks or a few months, at which time obstetric care has often ended. This leaves a certain number of uncared for women in whom infection persists for years. Surveys of pyelonephritis in all types of patients indicates that recurrent and persistent infections appear to be more potent in production of major degrees of remote damage than can be ascribed to the acute stages of infection with which the illnesses begin. That concept remains tenable in the sulfonamide era. It is not to be construed as indicating that minimizing the severity of the initial infection and limiting its duration do not soften the blow. This has been made possible by the sulfonamides.

REPORT OF CASES

CASE 1—History—Mrs. E. C. aged 30, mother of two children had a short attack of pyelonephritis involving the right kidney eight years ago during her first pregnancy. It was severe while it lasted. It is presumed from the subsequent history that cure was not produced. Two years later she was given sulfanilamide for bladder symptoms. Six years ago she had paralysis, involving her bladder, due to encephalitis from which she appeared to recover entirely within a few months. Two years ago she had a second pregnancy in which severe pyelonephritis symptoms confined to the right kidney developed early in the gestation. In spite of repeated courses of sulfadiazine and sulfathiazole there were frequent recurrences of fever and pain in the right kidney. The urine was never clear. All symptoms seemed to subside after delivery. About three months after delivery both the renal pain and bladder frequency returned and have been troublesome since that time.

Examination—There was no remnant of paralysis. There was tenderness over the right kidney but no mass. The urine showed pus and many bacilli.

Cystoscopy—There was no bladder residual. The mucosa was chronically inflamed. Both ureteral orifices appeared normal except for edema. There was a residual urine of 15 cc in the right pelvis. The urine was cloudy as was that in the bladder. The urine from the left kidney was clear. Phenol-sulfonphthalein excretion from both kidneys was prompt and of good concentration and approximately equal from the two kidneys.

Pyelography—The use of the retrograde method showed a normal pelvis and ureter on the left. On the right there was considerable dilatation of the pelvis and the whole of the upper third of the ureter. The lesion was not characteristic of a congenital defect and was of ureteritis.

Treatment—A series of ureteral dilations were done. These produced neither diminution in the residual urine nor improvement in the appearance of the pelvis and ureter. These were followed by two courses of six days each of sulfadiazine. One of these appeared to produce normal urine but infection was present two weeks later. The other made no improvement in the urine at all.

It is almost certain that nephrectomy will eventually be required. While there is no pyelography available previous to child bearing there is no urinary history either relating to childhood or early adult life up to the time of conception.

CASE 2—History—Mrs. P. S. aged 28 was examined by intravenous pyelography two years before marriage because of symptoms which were finally diagnosed appendicitis. The report from that examination (the films were not seen by me) described the kidneys as normal in appearance and function. Five years

From the Urological Clinic of the Boston Lying-in Hospital. Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Urology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

ago the patient had pyelonephritis in the fifth month of her first pregnancy. Labor was induced after sulfanilamide therapy had failed to produce subsidence of symptoms. Intravenous pyelography, also from the report of the x-ray department in a neighboring hospital, showed only a minor degree of renal dilatation. All symptoms subsided promptly after abortion. There was no evidence as to whether she then became free of infection. At any rate she remained free from symptoms of any kind for two years. At that time right sided pain developed for which her appendix was removed without relief. There was no frequency of urination, although reference to the record of the hospital in which the operation was done showed her to have had infected urine at the time of appendectomy.

Two years ago she again became pregnant. The right sided pain became worse during the first months of pregnancy but ceased about the fifth month. Fever never of severe degree, appeared between the fifth and sixth months of gestation, for which she had repeated courses of sulfathiazole. These treatments produced afebrile periods but did not clear the urine of bacteria. They ceased after delivery.

The right renal pain was absent for about one year after delivery of the second child. After that date it returned with greater severity than at any time previously. There were no fevers with these attacks.

Examination—This elicited some tenderness in the right renal region, but there was no mass. The urine showed a few pus cells and many bacteria.

Cystoscopy—There was no bladder residual, although the supports of the bladder were weakened on the left side and there was pouching. There were chronic inflammatory changes throughout the bladder mucosa. There was a residual urine of 8 cc in the right pelvis but none in the left. The urine from the right pelvis was cloudy and from the left clear. Cultures from the right showed bacilli and from the bladder also, but that from the left showed no growth.

Pyelography—The intravenous method showed dye appearing in both pelves at five minutes, with the greatest concentration of the dye at fifteen minutes on the left but at forty-five minutes on the right. There was residual urine in the right pelvis at the end of one hour. A film of the bladder after voiding showed no bladder residual.

Treatment—After a series of five ureteral dilations with number 9, 10 and 11 bulbs the residual urine in the pelvis was 2 to 3 cc in amount. Sulfadiazine therapy for six days produced negative cultures. During three months while the patient was under observation there was neither further renal pain nor a return of the infection. She will be observed at six month intervals.

PRESENT POLICY OF SULFONAMIDE THERAPY

Treatment of urinary infections during pregnancy are carried out in both outpatient and house cases. There seem to be no contraindications to treating some patients in the outpatient department. Those so treated are patients without fever in whom evidence, through catheter urines, is found of either pus or bacteria or both. Since most of our patients are a controlled group, are on increased fluid intake during pregnancy as a part of hospital policy and are seen regularly in antepartum clinics and at home if in trouble, the majority of admissions of infected patients are through the outpatient department. Some of these have had no symptoms of any kind and the finding of infection has been through routine examination of urine. In others, after a day or two of mild urinary symptoms at home, the patient has been seen by the district nurse and the house officer and sent to the outpatient department as soon as temperature is normal. Increased fluid intake is thought to be responsible for

the mildness of symptoms in these cases. As outpatient cases they receive sulfathiazole or sulfadiazine in 2 gram doses daily for six days with 60 grains (4 Gm) of sodium bicarbonate three times daily. The fluid intake is kept at 2,500 to 3,000 cc of water in addition to other fluids. If they become febrile while under outpatient treatment they are referred as house cases. A few febrile patients are admitted through reference by physicians and our own house staff directly to the hospital.

Febrile patients in the hospital are treated less routinely and more in accord with their condition at admission. Emphasis is placed on alkalization of the urine and obtaining adequate fluid intake as the first measure of treatment even though it means delay in instituting antiseptics. A fluid intake even in a desiccated patient of 3,500 to 4,000 cc and sufficient alkali to meet the demands for alkalinity of the urine is usually obtained within six to twelve hours after admission. As soon as this is accomplished, sulfadiazine or sulfathiazole is started. The initial dose is commonly 4 Gm for the first day and 2 Gm daily for the next five or six days. Seldom is drug therapy continued beyond that period at one time even if cure is not accomplished. If the acute symptoms do not subside we prefer to keep the patient on high fluid intake and resume treatment at a later time after some degree of tolerance for infection has been acquired. Complications from the drug appear to be commonest in protracted therapy and, in addition, further treatment adds little to the chance of clearing the infection. There is also virtue in awaiting development of antibodies by the patient. Under this regimen we find little use for intravenous administration of the drugs.

The degree of dilatation of pelves and ureters which patients develop appears to bear little relation to efficacy of therapy except in extreme instances of atony and distention of the pelves and ureters. The following histories are illustrative.

CASE 3—Mrs. A. J., a quintipara aged 33 had previous pregnancies in 1935 and 1936 in another hospital and in 1938 under her own physician's care which were all uncomplicated. A miscarriage occurred at two months in 1941. This miscarriage was followed by dilation and curettage. She was now in the sixth month of gestation.

Urinary findings and not symptoms indicated her condition. The blood pressure ranged from 120/70 to 132/80. Albumin was 2 plus, and there were some red blood cells and a few casts in addition to many bacilli and 5 to 10 pus cells noted in the urine. She was considered to have both preeclampsia and urinary infection and was referred to the hospital for medication.

Intravenous pyelography showed a moderate degree of dilatation of the right ureter and pelvis but only a small degree of change in the left ureter and pelvis.

Treatment was for but five days with sulfadiazine 2 Gm daily with sodium bicarbonate but with a fluid intake limited to 1,000 cc in deference to her preeclamptic state. The urine cleared of pus, bacilli and blood, but there remained albumin and a few casts.

CASE 4—Mrs. W. C., a tertipara aged 27, had her first pregnancy without complications in 1939. She had retention of urine post partum. The resulting cystitis was cleared in seven days with 80 grains (5 Gm) daily of sulfanilamide. The second pregnancy was uncomplicated. The urine remained normal throughout the whole of gestation and the puerperium.

Gross hematuria marked the onset of pyelonephritis in the fifth month of the fourth pregnancy. The organism was a

bacillus. There was no fever by the third day of bleeding when treatment was instituted.

Intravenous pyelography showed pronounced dilatation of the right pelvis and upper ureter. There were but small degrees of change in the left pelvis and ureter. Both the bleeding and the infection cleared on six days of treatment with 2 Gm daily of sulfadiazine with sodium bicarbonate on an intake of 2,500 cc of fluid daily.

She finished her pregnancy without further infection or bleeding.

Patients who fail to clear under routine therapy receive further investigation except when they are near to term and free from symptoms. In the latter cases intravenous pyelography is usually done to exclude renal conditions which might complicate delivery. Such patients occur in both the outpatient and the house groups.

Debility, of which anemia is the commonest cause but which may also be the result of overwork, undernourishment or poor toleration of pregnancy, is a common cause for failure of treatment. Such patients under appropriate treatment for anemia, dietary care and social service may readily clear of infection when treated at a later time.

Acquired tolerance for infection may account for some patients who are easily cured as outpatients after having failed to become clear of infection when treated during their febrile stages as house patients. The intervals between courses of therapy is commonly two to three weeks. A few patients have been noted who were discharged from the hospital after antiseptics with both bacteria and pus still present in their urines who appeared to clear spontaneously in the interval.

Sulfonamide resistant bacteria are usually assigned a role in certain patients who resist cure. It is not easy to assess this factor. In some patients it is not possible to diminish symptoms or cure infection. These cases account in part for the rare instances of interruption of pregnancy for therapeutic reasons. We have made use of succinylsulfathiazole in 18 gram doses daily over periods of two to three weeks with but limited success.

Gross pathologic changes are responsible in the majority of patients who fail to clear under treatment. Not all degrees of abnormality defeat therapy.

CASE 5—A primipara aged 19 was admitted to the hospital because of rise in blood pressure to 180/138. Urinary infection was discovered on admission. Diagnosis was preeclampsia grade 1. The patient was kept in bed, fluids were limited to 1,500 cc daily and 2 Gm of sulfadiazine was administered with sodium bicarbonate 60 grains (4 Gm) daily for six days. The infection cleared and the blood pressure fell to 120/74 in the eleven days of her stay in the hospital. An intravenous pyelogram showed the left kidney to be unrotated and moderately hydronephrotic. She continues in the outpatient department with a clear urine and a reasonable blood pressure.

CASE 6—A tertipara aged 25 had no history of urinary infection preceding her first pregnancy in 1939. She had had pyelonephritis in pregnancy at home in the care of her own physician from May to August. Her urine was very purulent, but she was then afebrile. She was admitted directly to the hospital because due. No pyelography was done before delivery, which was made immediately on admission. Delivery was followed by retention of urine and postpartum pyelonephritis. She was given 60 grains (4 Gm) daily of sulfanilamide for twenty-four hours, then 40 grains (2.6 Gm) daily for six days. In the meantime she was kept on constant drainage. The urine was still clear of infection when last seen after that pregnancy and puerperium in the sixth month after delivery. Her second

pregnancy was in 1942. The urine remained normal throughout the whole of this pregnancy and puerperium. In her third pregnancy, while under supervision in the outpatient department infection appeared in the sixth month. The urine became very purulent but she remained afebrile. The urine did not clear on 2 Gm of sulfadiazine daily for six days. Retrograde pyelography showed her to have a double right kidney, the upper half of which was hydronephrotic. She remains infected but afebrile. She is due for corrective surgery after delivery.

CASE 7—A primipara aged 18 without urinary symptoms at any time in her life previous to pregnancy, was discovered to have bacilluria during the third month of gestation. The urine did not clear under 2 Gm of sulfadiazine with sodium bicarbonate daily for six days administered in the outpatient department. This course was repeated in two weeks. Intravenous pyelography showed extensive dilatation of both pelvis and ureters throughout their upper two thirds and large dilations of the lower portions near to the bladder. There is no evidence of renal insufficiency, she remains afebrile and there is little pus in the urine, although bacilli are abundant. She continues in pregnancy under careful observation especially for evidences of renal insufficiency. It is possible that interruption may become necessary before her pregnancy is finished. She is to have urologic treatment after delivery.

In the latter cases important urologic findings may be missed to the detriment of the patient in later life. Intractable infections are apt to occur in them in subsequent pregnancies and the gross lesion be discovered at that time. In instances in which there are extensive alterations from the normal which are brought to notice for the first time through the onset of infection interruption of the pregnancy may be necessary. Interruptions of pregnancy for urinary causes alone, eliminating those patients who have both urinary infection and another condition such as preeclampsia, now result in an average of but one abortion per year in a clinic in which from 4,000 to 5,000 deliveries are cared for.

Intravenous or retrograde pyelography is not employed for all patients who have urinary infection. It is routine for all lone kidney patients, those with histories of renal stone and hydronephrosis, those with infections already present at the beginning of pregnancy, cases of renal tuberculosis and all who have had renal surgery. Beyond these routine cases it is employed for all patients who do not clear their infections under treatment, who show gross hematuria or who present unusual initial symptoms.

Urinary infections are frequent complications of other conditions the nature of which necessarily modifies therapy for the infectious process. These are heart disease, diabetes and preeclampsia. Because of the undesirability of forcing fluids in preeclampsia and cardiac decompensation, antiseptics with limited fluids is sometimes necessary. In spite of strict limitation of fluids during treatment in these cases and large doses of the sulfonamide drugs, which are administered in pneumonia and uterine sepsis, there has not been to date any case of blockage of the urinary channels with crystals such as has become common in the nonpregnant. The patients treated in obstetric hospitals are either pregnant or recently pregnant patients whose urinary channels still exhibit some degree of modification due to the pregnant state.

Progress in management of diabetes in pregnancy has made possible treatment of these patients by almost the same routine as that for nondiabetic patients with equally good results. Preeclampsia is the most com-

monly encountered complication of infections in the urinary tract. The combination of these two diseases accounts for interruption or abortion in about 4 cases to 1 for uncomplicated urinary infection. Sulfonamide therapy appears to do no harm to patients with toxemia who do not have nitrogen retention.

Since the introduction of the sulfonamide drugs, renal inadequacy from severe pyelonephritis appears to have been eliminated. If the infection cannot be cured in these cases, it can almost always be rendered asymptomatic and the acute involvement of the renal parenchyma greatly reduced in severity. When renal inadequacy is encountered nowadays one should suspect gross pathologic change in the kidneys.

Cystoscopy for pyelonephritis in pregnancy is now much less frequently employed than before the sulfonamides. There are a few patients in whom lavage of the pelves to remove massive purulent material is beneficial either before or during treatment with the sulfonamides, but this procedure is now essentially diagnostic. Most kidneys in pregnant women have sufficient renal substance to permit self clearance if adequate fluid intake is provided, without resorting to artificial means.

Except in obstructive ureteral calculus, renal and ureteral stones are reasonably well tolerated when the severity of the attending pyelonephritis is minimized by the sulfonamides. In obstructing calculi it is sometimes possible to manipulate the calculus cystoscopically and provide drainage. Stone is now most commonly treated surgically after delivery.

SUMMARY

The sulfonamide drugs have greatly modified the management of pyelonephritis in pregnancy for the better. Determination of the exact degree of benefit which these drugs have made possible cannot be made until surveys of patients at from five or more years from the time of infection have been compiled.

Sufficient experience has been accumulated to indicate that the beneficial effects of these drugs in ameliorating symptoms can be expected to take place in almost all patients whether or not cure of the infection is accomplished. A high percentage of patients have their urines rendered sterile both in uncomplicated cases and in those with complicating diseases and with safety to the patient.

Among the uncured cases are some in which persisting infections are producing extensive damage to the efferent channels and can be expected to do so eventually to the renal cortex similar to those shown in surveys of patients from the previous regimens. These are preventable.

There are two major defects in obstetric practice as I see the problem in relation to pyelonephritis. One is failure to investigate urologically those patients who do not obtain cure through sulfonamide therapy for detection of gross pathologic conditions. The other is that many women leave obstetric care with urines still infected from which, in subsequent years, through long continued or repeated acute injuries, preventable gross damage to the urinary tract results.

Optimism based on apparent cures of pyelonephritis in pregnancy following delivery which was responsible for the high percentage of abnormal urinary tracts found after five or more years in the presulfonamide era has its corollary in the sulfonamide era when prompt

subsidence of symptoms appears to be mistaken for cure. Similar cases to those already described in previous reports are occurring in sulfonamide treated patients. Let us hope that surveys will show that the number of such cases is greatly reduced in comparison with published end results.

99 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR J P GREENHILL, Chicago. The word pyelitis is commonly used for the subject under consideration, but, as indicated in Dr Crabtree's title, there is damage to the kidney in most cases, hence the correct term is pyelonephritis. Likewise the ureter is generally involved, so there is really a pyelonephritis and ureteritis. There is a tendency for so-called cured or relieved pyelonephritis to flare up during the puerperium in at least half the cases. If the urinary infection is present longer than three months after delivery it is almost certain that there is a gross pathologic condition present and a complete study of the urinary tract must be made. Even if the infection is cleared up, a complete study of the urinary apparatus should be made before a new pregnancy is planned, because a woman who has had pyelonephritis in one pregnancy has about one chance in four of developing this complication in a subsequent pregnancy. Contrast this with the usual incidence of pyelonephritis in pregnancy of 1 in 50 cases. If a new pregnancy begins before the urinary infection is cleared up, the chances of recurrence are one in two. Many women have permanent defects such as hydronephrosis and hydroureter following a single attack of pyelonephritis. The treatment of pyelonephritis by means of the sulfonamides is now relatively simple, but, as Dr Crabtree points out, we must be extremely careful in evaluating our results. In addition to the sulfonamides we must overcome anemia which is fairly common, we must avoid constipation, use the Fowler position for proper drainage, force fluids and give sedatives, we must treat the patient as we did before we had the sulfonamides. The sulfonamide treatment has no bad effect on the babies, and by means of this therapy nearly all patients can be carried to term. As emphasized by Dr Crabtree, there is apparently no danger that pregnant women will develop a urinary block by crystals if the amount of fluids is not greatly increased. There is now rarely any necessity to employ ureteral catheterization or to empty the uterus because of pyelonephritis, but we must remember that the sulfonamides will not cure all patients who have pyelonephritis, hence in an occasional case the pregnancy may have to be terminated. It is difficult to prevent the first attack of pyelonephritis except by removing foci of infection. Much can be done in a prophylactic way by routine microscopic examination of every pregnant woman's urine at every office visit (or oftener when indicated). Once a woman has had pyelonephritis, not only must she be carefully checked for a long time following the first attack but also her urinary tract must be studied before each new pregnancy. Prophylactic therapy with the sulfonamide drugs in successive pregnancies will certainly reduce the incidence of severe recurrences and produce rapid cures, because the patients can be treated early.

DR BUDD C CORBUS, Chicago. In November 1927 W C Danforth, head of the department of obstetrics at the Evanston Hospital, and I reported our findings in the so-called pyelitis of pregnancy. Our conclusions at that time were as follows. The termination of pregnancy does not cure the urinary infection. These cases should be studied and treated after the pregnancy ends in order to restore adequate urinary drainage if possible. As a pathologic condition of the urinary tract was shown to exist after termination of pregnancy, in all cases studied it seemed reasonable to assume that obstructive pathologic changes may have been present before the pregnancy began. There is no doubt that the pressure of the fetal head and the hormonal influence on the ureter causing dilatation, with lessened

peristaltic action accompanied by urinary stasis, may be a contributing factor in pyelitis; however, if this was a significant factor more pregnant women would have complicating pyelitis. To me it is the question of the straw breaking the camel's back. I think we can truly consider that pyelitis of pregnancy is a clinical exacerbation of a previous latent chronic urinary tract infection, and in demonstrating this we should not forget the modern conception of the possible pathology of the female bladder neck. We are all aware in urology of the value of the sulfonamide drugs for the nonpregnant woman; we know, however, that they are dangerous and that their administration should be well supervised. The use of drug therapy during an attack of pyelitis of pregnancy by no means replaces complete urologic study after the pregnancy has terminated.

DR A. J. KOBAK, Chicago: All cases of pyelitis occurring in the obstetric services of Cook County Hospital were studied during a period of twenty-one months and our findings were published. Our material consisted of 143 cases, an incidence of 1.63 per cent. Ninety-five patients had pyelitis ante partum and 48 during the puerperium. It was necessary to interrupt the pregnancy of only 1 patient, and there were no mortalities in the series of cases studied. However, this good fortune was short-lived, because subsequent to this report we had three deaths. These patients had more than a simple pyelitis—a pyelonephritis. One woman pregnant for six and one-half months, who had a clinically mild pyelitis, developed pyelonephritis and then eclamptogenic convulsions. The autopsy revealed typical toxemia changes in the liver. The second patient developed pyelonephritis following the birth of a premature baby. The temperature reached a 106° F. level, and the postmortem findings indicated changes in the kidney parenchyma and those of a generalized sepsis, although we never obtained a positive blood culture. The remaining patient four and one-half months pregnant aborted spontaneously, shortly after her admission. She bled sufficiently to warrant a uterine packing. She died after a period of complete urinary suppression and with postmortem evidences of a severe ascending pyelonephritis. All 3 patients had retention of nitrogenous products by blood chemistry analysis. More than one-third of the puerperal pyelitis in our reported group had etiologic factors that one frequently observes in patients who develop puerperal sepsis. Thus prolonged labors, difficult forceps deliveries and cesarean sections that were not elective were in this group. Also many of our pyelitis patients had concomitant puerperal sepsis. In view of the anatomic propinquity of the urologic and genital systems this is not surprising. I wonder if the author can shed any light on this thought that puerperal sepsis and pyelitis may bear a direct mutual relationship.

DR E. GRANVILLE CRABTREE, Boston: Dr. Kobak, in the reporting of three deaths, brings into prominence the reasons for intensive study that have existed all along and underlie these publications, which is that the handling of these cases in all their complications is not yet simple enough so that perfection can be acquired without the obstetrician becoming an industrious student of this subject.

Aristotle—Aristotle (384-322 B. C.), the most comprehensive mind of classical antiquity, may be said to have applied to general science the objective method of observation used by Hippocrates in clinical medicine. The other Greek scientists or natural philosophers, such, for instance as Heraclitus and Parmenides, indulged in vague speculation about the nature of the universe, without bothering to verify their fundamental data. Aristotle obviously made direct observations. He covered an immense field—physics, astronomy, meteorology, psychology, natural history. In biology his work on embryology (*De generatione animalium*) is full of acute observation, *Historia animalium* and *De partibus animalium* furnish a rough, fairly good idea of animal and human anatomy.—Clendinning, Logan. *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

CAFFEINE AND "PEPTIC" ULCER

RELATION OF CAFFEINE AND CAFFEINE-CONTAINING BEVERAGES TO THE PATHOGENESIS, DIAGNOSIS AND MANAGEMENT OF "PEPTIC" ULCER

CHICAGO

In this paper evidence will be presented which strongly indicates that the excessive use of caffeine-containing beverages may contribute to the pathogenesis of "peptic" ulcer in the ulcer-susceptible individual, may aggravate an ulcer already existing and may render the therapeutic management of the condition more difficult. Preliminary studies on ulcer patients suggest the use of a caffeine test meal in the diagnosis of peptic ulcer based on the prolonged secretory curve when the response to caffeine is expressed as the total output of free acid. Additional evidence suggests that a prolonged gastric secretory response to caffeine may provide a method for the detection of those persons who are predisposed to the development of "peptic" ulcer.

LITERATURE

Smoking and the consumption of alcoholic beverages have been interdicted in the management of "peptic" ulcer patients by internists for many years. The consumption of caffeine-containing beverages has not, as a rule, been restricted, except in some instances during the early phase of the management of the active ulcer.

There are several reasons why the relation of caffeine to ulcer and gastric secretion has been a neglected field of investigation. One reason is that caffeine does not stimulate gastric secretion in all species of animals. It does not stimulate gastric secretion in the dog.¹ And it has been shown only recently that caffeine stimulates gastric secretion in the cat.² Considerable disagreement is found in the literature concerning the effect of caffeine in man. Various authors³ have concluded that caffeine does not stimulate gastric secretion in man, whereas others⁴ have observed an increased output of acid gastric juice after caffeine administered orally or parenterally. The most recent reviewer of the subject⁵ erroneously concluded that caffeine does not stimulate gastric secretion.

Aided in part by a grant from the Clara L. Abbott Fund. From the Department of Physiology, Northwestern University Medical School.

The experimental design and technic used in some of the investigations on human subjects were poor in the light of current knowledge. That earlier investigators failed to show conclusively that caffeine has a definite stimulating effect on gastric secretion in man can in part be attributed to (a) insufficient exposure of the gastric mucosa to caffeine, (b) failure to wait long enough for intramuscular caffeine to produce its effect and (c) the fact that the stimulation of secretion by secretagogues in coffee, natural or produced by the roasting process, was not distinguished from the secretion due to caffeine.⁶ The peak of the response to the intramuscular administration of caffeine usually does not occur until sixty to seventy minutes after the injection, whereas, when caffeine is given as a test meal, the peak response occurs in from thirty to forty minutes.⁷ The prolonged increase in total output of hydrochloric acid in patients with "peptic" ulcer was missed by previous investigators. In order to demonstrate this prolonged response it is necessary to collect gastric secretion for a longer period than one hour and to determine the total output of free acid by multiplying the concentration of acid in the juice by the total volume of gastric contents aspirated (every ten minutes).

PRODUCTION OF GASTRIC ULCER IN CATS

Interest in the possible deleterious effects of excessive amounts of caffeine on the stomach was provoked by a recent report by Judd.⁷ Judd observed acute and subacute gastric ulcers in 40 to 50 per cent of cats when they were given caffeine in a beeswax-petrolatum mixture to insure the slow and more prolonged absorption of the drug. We⁸ have confirmed the work of Judd and have reported additional observations which may explain in part the pathogenesis of caffeine-induced ulcer.⁹

Direct observation of a mucosal stoma in the cat shows a persistent blushing (hyperemia) after the intravenous administration of caffeine, followed by cyanosis. Microscopic sections, made at the time when the mucosa grossly appeared more reddened thicker and succulent, showed apparent dilatation and engorgement of veins and venules of the submucosa. However, when the mucosa appeared cyanotic there was pronounced dilatation and engorgement of the mucosal venules. Continuous or repeated stimulation of gastric secretion in the anesthetized cat with histamine for ten to twelve hours produces no apparent change in the gastric mucosa. But, if caffeine (125 mg intravenously or by direct lavage of the stomach for thirty minutes) is alternated with the histamine (0.3 mg), large diffuse areas of epithelial desquamation and multiple bleeding erosions and ulcerations of the gastric mucosa are observed in as short a time as five hours. This alteration in the susceptibility of the gastric mucosa to the proteolytic action of gastric juice has been arbitrarily designated and attributed to "cellular toxicity." The latter may involve alteration in cell permeability or the concept of caffeine-histamine synergism. Thus the vascular changes and factor of "cellular

toxicity" are implicated in the pathogenesis of caffeine-induced ulcers in cats by increasing the susceptibility of the mucosa to the digestive action of gastric juice.

Comment—It is realized that these observations on the cat may not be applied directly to man. It is reasonable however to estimate how much caffeine might be required in man to produce similar changes in the gastric mucosa. Since 2 grains (125 mg) of caffeine in combination with "histaminergic" stimulation of gastric secretion (0.3 mg of histamine dihydrochloride alternately) was capable of producing acute ulcers in a 5 pound (2.3 Kg) cat, 60 grains (7.8 Gm) of caffeine would be required in a 150 pound (68 Kg) man on the basis of body weight. However, body weight comparisons are not always reliable. For example a dose of 0.5 or 1.0 mg of histamine stimulates gastric secretion in man and dog, a dose of 62.5 to 125 mg of caffeine stimulates gastric secretion in the cat, and 80 to 250 mg in man. It is reasonable to hypothesize that the daily consumption of 20 or 30 grains of caffeine over a long time (equivalent to ten to fifteen cups of coffee) may contribute to the development of "peptic" ulcers in ulcer-susceptible individuals. We have not had an opportunity to make observations on a patient with a gastric fistula or during gastroscopy.

THE GASTRIC SECRETORY RESPONSE TO CAFFEINE IN MAN: NORMAL SUBJECTS AND "PEPTIC" ULCER PATIENTS

The gastric secretory response to a "caffeine test meal" has been determined in 50 asymptomatic medical students and nurses and in 36 patients under management for "peptic" ulcer.

The ordinary gastric analysis is designed to answer one or two questions: (a) Does the stomach secrete free acid in response to a meal (Ewald or some modification)? (b) If not, is the stomach capable of secreting free acid in response to a more potent stimulus (histamine)? Since the "caffeine test meal" as used by us consists of more than the ordinary gastric analysis, and since it may prove to be of diagnostic or prognostic value, we shall briefly describe it.

The Caffeine Test Meal—After an overnight fast, the usual precautions regarding expectoration of saliva, the avoidance of retching by placing the tube between the teeth and the cheek and completeness of evacuation of the stomach at each period are followed. After removal of the residuum, a baseline from which stimulation can be measured is obtained by emptying the stomach every ten minutes for a control period of thirty minutes. The total volume recovered at each ten minute aspiration is measured and a sample (10 cc) titrated for free and total acid, expressing the latter in terms of the total volume aspirated (volume times concentration).

Then, 200 cc of warm water containing 0.5 Gm (7½ grains) of caffeine with sodium benzoate is introduced into the stomach through the tube. The resulting solution is slightly alkaline, having a pH of about 8.0. A "block" procedure was then followed for the analysis: for the next two ten minute intervals 10 cc samples were removed for analysis. The purpose in removing these samples was to detect the first rise in acid concentration and thus the latent period of stimulation. To simplify the procedure for clinical use, the aspiration of these two samples may be omitted. Thirty minutes after introducing the test meal, the residuum of the latter and whatever gastric secretion has accumulated is removed completely. The stomach is emptied at ten minute intervals thereafter for an additional ninety minutes or until the secretory response has subsided and the 'basal' level once again is obtained. The duration of the test is thus two hours and thirty-five minutes divided as follows: removal of residuum thirty minute "basal" control period five minute period required to introduce the test meal

thirty minute period of exposure of the gastric mucosa, and a ninety minute period of aspirations every ten minutes after removal of the test meal

Titration and Calculations—Titrate the 10 cc samples of gastric juice with thirty-sixth normal sodium hydroxide (may be made by the addition of 20 Gm of sodium hydroxide to 18 liters of water), using Toepfer's reagent and phenolphthalein as the indicators for free and total acid respectively. As 1 cc of thirty-sixth normal sodium hydroxide is equivalent to 1 mg of hydrochloric acid, the buret readings can be converted directly into milligrams of hydrochloric acid. To obtain the total output of free and total acid, the buret readings are divided by 10 to give the number of milligrams of hydrochloric acid per cubic centimeter of gastric juice and multiplied by the volume aspirated. The accuracy of the test thus depends on the ability of the technician to empty the stomach of its contents completely which is relatively easy.

Buret reading = mg HCl/10 cc gastric juice (sample)

Total output of acid = $\frac{\text{buret reading}}{10} \times \text{total volume aspirated}$

* No figures appear for the second hour since the response had returned to the basal level within sixty minutes

Response of Normal or Asymptomatic Subjects—Three types of response were obtained in the normal or asymptomatic subjects when the data were plotted as a "total output of acid curve." Thirty-seven, or 75 per cent showed an abrupt, transient stimulation with a peak followed by a return to the control level within sixty to seventy minutes (chart 1). In 15 per cent a low flat curve was obtained which returned to the control level in seventy to eighty minutes (chart 2).

The remaining 5 subjects, or 10 per cent, showed a prolonged secretory response (chart 3). It is noteworthy that 3 of these 5 subjects have since developed epigastric distress simulating ulcer, and in one a prepyloric ulcer has been found by x-ray (table 1).

The Response of Ulcer Patients—Of the 36 patients studied 30 had proved duodenal ulcer and 6 gastric ulcer.¹⁰

All of these patients, with the exception of 1, have consistently shown a prolonged response to the caffeine test meal (charts 4 and 5). Though the cases are relatively few, there is a greater tendency for the gastric ulcer patient to return to the control level toward the end of two hours than the duodenal ulcer patient.

The Response of Special Cases—The data in table 1 are presented to illustrate the individual variations and range in response to a caffeine test meal in the various groups of normal subjects and ulcer patients. It is to be noted that where the acid output for the second hour remains high this reflects the prolonged secretory curve in which a high level of acid is maintained (charts 3, 4 and 5). Certain of the cases have been selected to point out particular features in the use of the caffeine test meal for the diagnosis of ulcer. Patient H P, partially obstructed at the time the test was performed, showed an absence of free acid in the "basal" control period but maintained a stimulation of gastric secretion at a relatively low level throughout the test. Not all patients with a prepyloric ulcer show a tendency for the secretory response to return to the basal level toward the end of the two hours as demonstrated in the case of L F. The highest magnitude of stimulation in this series of ulcer patients was obtained in W M, three weeks after the test was performed the patient developed an acute perforation. Patient J J, with the diagnosis of catatonic schizophrenia, was admitted to the hospital after a

severe attack of hematemesis with a red blood cell count of 2 000 000. The anamnesis and x-ray examination of the stomach and duodenum gave no indication of peptic ulcer, but the prolonged secretory curve in response to caffeine confirms the most probable cause of such severe hemorrhage in a man aged 24 in whom no cause could otherwise be demonstrated. This instance illustrates the most useful application of the caffeine test meal where other laboratory aids fail to confirm the history or where a silent ulcer is revealed. The low volume of gastric juice recovered during the test on patient C T indicates rapid emptying through the pylorus, but the concentration of acid (milligrams of hydrochloric acid per cubic centimeter) remained elevated throughout the test. This has been interpreted as consistent with the ulcer response since normal subjects show a return to the 'basal' concentration as well as to the 'basal' total output of acid, although the differences between normal and ulcer concentration curves (clinical units) are not as great as in total output curves (chart 6). Only 1 of the group of 36 ulcer patients studied showed such rapid emptying of the stomach as to present the foregoing picture.

Comparison of Responses of Ulcer Patients to Alcohol and to Caffeine—Rehfuß according to Bockus,¹¹ was the first to observe the tendency for patients with duodenal ulcer to manifest a prolonged or "terminal" response to a test meal. This has been reported by

10. The majority of the ulcer patients used in this study were provided by Drs. Arpinus Baker, Carroll and Frauba at the Hines Veterans Hospital.

11. Bockus, H. L. Gastroenterology, Philadelphia, W. B. Saunders Company, 1941, vol. 1, p. 407.

others¹² In their studies the concentration of acid in clinical units was followed. In our work, as in laboratory animals, we have calculated and used the total output of acid secreted. We believe this to be preferable because the total output of acid is a truer index of the secretory response than the concentration of acid. To

Chart 1—Composite curves on 37 normal subjects (75 per cent) showing abrupt transient stimulation of gastric secretion in response to caffeine test meal.

do this with the intact stomach a 'block' procedure (vide supra) is required since it cannot be done by the 'sampling' technique.

Because the alcohol test meal is frequently used and because alcohol is frequently interdicted in patients with 'peptic' ulcer, we have compared alcohol with caffeine as gastric stimulants. Ten of the peptic ulcer patients were given the alcohol (200 cc 5 per cent) and caffeine test meals. Twenty-five normal asymptomatic subjects were similarly studied. In each case the 'block' procedure as described was used. The composite 'total output of acid' curves of normal subjects and 'peptic' ulcer patients are shown in chart 7.

In both groups an abrupt transient stimulation with a peak and return to the control level within sixty to seventy minutes occurred in response to alcohol.

Chart 2—Composite curves on 5 normal subjects (15 per cent) showing low flat secretory curve in response to caffeine test meal.

Although the average magnitude of the response to alcohol is higher in the duodenal ulcer patients the shape of the curves and the duration of the responses are the same. Since the magnitude of the response to alcohol in normal subjects and 'peptic' ulcer patients

overlap so decidedly in the two groups the differences are not statistically significant and are of little differential value. This was not true of the caffeine test meal except in 10 per cent of asymptomatic subjects who apparently have a predisposition to 'peptic' ulcer.

Comment—Although sufficient evidence has been presented to show that the stomach of the 'peptic' ulcer patient especially the duodenal ulcer patient manifests a more prolonged response to caffeine than that of the 'normal' subject certain questions are still open. A sufficient number of duodenal ulcer patients have not been studied to ascertain if all will show a prolonged response. A sufficient number of gastric ulcer patients have not been studied to ascertain if they as a rule respond differently from duodenal ulcer patients. Whether the response of duodenal ulcer patients to the caffeine test meal returns to the normal type during a remission has not been determined.

Our results suggest that it would be valuable to determine with what degree of accuracy predisposition to 'peptic' ulcer may be predicted by the response to the caffeine test meal. In this connection one should recall the observations of Todd¹³ on medical students.

Chart 3—Composite curves on 5 normal subjects (10 per cent) showing prolonged response at a high level of acidity like the ulcer patient.

He found (a) that a small group of students responded to anxiety by manifesting a hypermotile and hypertonic stomach and (b) that it was only in this group that duodenal ulcer developed sometime during the medical course.

The practical points which we believe our data establish are that caffeine causes a prolonged response in duodenal ulcer patients, and it would seem to be indicated that this fact should be considered in the management of such patients.

CAFFEINE ACTS SYNERGISTICALLY WITH HISTAMINE OR ALCOHOL

It has been reported elsewhere that caffeine acts synergistically with histamine or alcohol.¹⁴ This matter was studied for practical as well as for academic reasons.

First, why does caffeine cause a prolonged gastric secretory response in patients with 'peptic' ulcer? There is strong presumptive evidence showing that the phase of gastric secretion which cannot be inhibited by atropine is due to the production of histamine.¹ If

the ulcer patient produces histamine and since histamine and caffeine act synergistically, this would explain the prolonged response of the ulcer patient to caffeine. It has been shown¹⁴ that when the two drugs are given together to a nonulcer subject the magnitude of the

beverages selected for study included coffee, coffee with sugar (10 Gm) and cream (30 cc, 18 per cent), "Sanka," "Postum," "Coca Cola" and tea. An attempt was made to make the preparations of the beverages uniform by using a constant weight of the dry product per unit volume and by being consistent in the time of extraction. Each beverage was prepared according to the directions on the label of the product. The volume of the beverages used for test meals in the studies was

TABLE 2—Average Caffeine Content of Various Beverages

Beverage ¹	Approximate Caffeine Content	
	Mg /Cup or Bottle	Grains/Cup or Bottle
Coffee	100-120	1½-2
Coca Cola	77	1¼
Spur	57	¾
Tea	17-30	¼-½
Sanka	8-17	⅛-¼

Chart 4—Composite curves on 30 duodenal ulcer patients showing a prolonged stimulation at a high level of acidity in response to caffeine

combined response is greater than the sum of the responses to the drugs given separately and the response is definitely prolonged.

Since alcohol, according to strong evidence stimulates gastric secretion by causing the release of histamine,¹⁵ it is not surprising that alcohol and caffeine act synergistically on gastric secretion. This observation would caution against the mixing of caffeine-containing and alcohol-containing beverages by persons with a predisposition to "peptic" ulcer.

RESPONSE TO CAFFEINE-CONTAINING AND SUBSTITUTE BEVERAGES

After studying the gastric secretory response to pure caffeine in normal subjects and ulcer patients, our attention was directed to the practical problem of the

Chart 5—Composite curves on 6 gastric ulcer patients showing a tendency to return to basal level during the second hour period

response to various caffeine-containing beverages and substitute beverages.

Method—The same procedure as outlined for the caffeine test meal was used in these studies. The

300 cc, which is approximately the volume of two average cups. The average caffeine content of various beverages appears in table 2.¹⁶ It is apparent from this table that 2 cups of coffee contain approximately the same amount of caffeine as used in the caffeine test meal (250 mg caffeine base). As the color of the beverage interfered with colorimetric titrations, it was necessary to do electrometric titrations, using as an end point

Chart 6—Comparison of free acid response to caffeine test meal in normal (75 per cent) and duodenal ulcer patients. The same data are plotted both as total output and as concentration (clinical units). The sustained total output of free acid suggests the ulcer diagnosis; the concentration curves are less reliable for diagnosis because of greater tendency for overlap.

for free acid and total acid a pH of 3.5 and 8.5 respectively.

Results—The average free acid response to these various beverages in the same 10 normal individuals is presented in graphic form in chart 8. It is apparent that all of the beverages stimulated gastric secretion less than an equal volume of coffee. Comparing the total output of free acid from each of the beverages with that from coffee for a period of seventy minutes, the average response to tea was 60 per cent, to "Postum" 59.3 per cent, to coffee with sugar and cream 59.7 per cent, to "Sanka" 75.3 per cent and to "Coca Cola" 89.5 per cent of the response to coffee. Although "Sanka" contains relatively little caffeine, it provokes

considerable stimulation of gastric secretion presumably because of its content of other secretagogues ("Sanka" because of its secretagogue rather than caffeine content stimulates gastric secretion in the dog caffeine does not). We have confirmed the report that a so-called decaffeinated coffee preparation stimulated gastric secretion in patients with hyperchlorhydria and "peptic" ulcer about the same as coffee.¹⁸

In chart 9 appears the total output curves for free acid in response to coffee (300 cc) in both normal subjects¹⁹ and duodenal ulcer patients.²⁰ The ulcer patients have consistently shown a prolonged secretory response to the coffee test meal maintaining a high level of acidity at the termination of the test. However, in the few instances in which it was tried a coffee substitute which contains no caffeine did not provoke a hypercontinuous secretion of gastric juice.

Comment—It is believed that the foregoing observations warrant the following recommendations in the management of the "peptic" ulcer patient. The consumption of caffeine-containing beverages

apparently render the mucosa susceptible to erosion such beverages should be avoided by the ulcer patient. This is particularly true of their excessive use. It is realized that the psychologic hardship of total abstinence is sometimes more aggravating to the ulcer patient than

Chart 8—Composite free acid curves in response to related beverages in 10 normal subjects. The column show the free acid response to the beverages when compared to the coffee response in percentage.

the pharmacodynamic effects of a contraindicated substance. In such instances a single cup of coffee with sugar and milk or cream with the meal could be allowed. Or one might substitute a beverage of lower caffeine content such as tea or some coffee substitute some roasted cereal product low in those secretagogues produced by roasting.

CONCLUSIONS

- 1 Caffeine in relatively large doses causes acute and subacute ulceration of the gastric mucosa in cats.
- 2 Caffeine (80 to 250 mg) stimulates gastric secretion in man and the cat but not in the dog.
- 3 Caffeine acts synergistically with histamine or alcohol in stimulation of gastric secretion in man and the cat.
- 4 Caffeine-containing beverages stimulate gastric secretion in man. Coffee substitutes produced by roasting cereal contain secretagogues which stimulate gastric secretion in man. Coffee stimulates gastric

Chart 7—Comparison of free acid response to alcohol test meal in normal and ulcer patients. The similarity in the shape of the curves and the overlap in magnitude of response limits the use of the alcohol test meal in diagnosis.

ages should be restricted to a minimum in view of the magnitude and duration of the gastric secretory response. If small amounts are allowed, they should be taken with cream and sugar. In our series of 36 ulcer patients 70 per cent reported that they had observed that coffee aggravated their symptomatic distress.

It is well known that much sound clinical judgment and persuasion must be exercised in the management of the patient with "peptic" ulcer. It should be clear that because a substance stimulates gastric secretion this in itself is not a sound reason for its interdiction. Otherwise we should interdict protein food which serves an important role in the therapeutic rationale of frequent feedings with milk and cream.

Since caffeine and caffeine-containing beverages do not provide a "buffering effect" but provoke a prolonged secretion of acid in ulcer patients and since caffeine produces vascular and "cellular" changes which

Chart 9—Comparison of the free acid response to a coffee test meal in normal subjects and duodenal ulcer patients. Note the sustained stimulation in the ulcer patients in contrast to the abrupt transient response in normal subjects.

secretion because of its caffeine content and because of other secretagogues (natural roast products or irritant volatile oils).

5 Caffeine and caffeine-containing beverages provoke a prolonged increase in the total output of acid by the stomach in patients with "peptic" ulcer.

6 Five of a group of 50 'normal' or asymptomatic human subjects responded to the caffeine test meal like an ulcer patient. Three of the 5 have subsequently developed the ulcer type of distress, and 1 of these has developed an ulcer as demonstrated by x-ray.

7 The evidence indicates that the excessive use of caffeine-containing beverages may contribute to the pathogenesis of "peptic" ulcer in the ulcer susceptible person and will render the therapeutic management of the condition more difficult.

ABSTRACT OF DISCUSSION

DR A F R ANDRESEN, Brooklyn After experimenting with coffee in ulcer patients, I began thirty years ago to forbid its use in ulcer diets and have continued to do so ever since. This in contradistinction to smoking, which I have found is rarely harmful and then probably explainable on an allergic basis. The demonstration that caffeine given to human beings will produce an acid curve of continued secretion in a series of fractional removals of gastric contents thereafter is an indication of irritation. The similar curve, a continued or rising secretion for a period of two hours or more following injection of histamine instead of the normal, physiologic rise and fall after one hour, has been demonstrated in most ulcer cases and we have always explained it on the basis of gastric irritation produced by the presence of the ulcer. Histamine appears to be a physiologic stimulant to gastric secretion, Ivy having demonstrated its identity with gastric hormone, and is therefore the best stimulant to secretion that can be used in gastric analysis. The combination of an irritant such as caffeine with the histamine would not seem advisable as a routine procedure, as the response would not be a good test of the patient's usual secretory habits. The suggestion that human peptic ulcers may be caused by the taking of caffeine does not seem to be justified, although sudden excessive consumption of caffeine by patients subject to the development of ulcers might conceivably be the irritant which started an attack. The diffuse areas of superficial erosion or sloughing seen in the experiments on the cats evidences of a poisoning, do not at all resemble discrete human peptic ulcers. Prevention of ulcers by abstinence from caffeine is not borne out clinically. If other factors tending to produce an ulcer have not been eliminated, abstinence from caffeine has not prevented their recurrence and I have found that patients whose focal infections have been thoroughly eradicated can drink coffee with impunity.

DR THEODORE J CLARNEY, Garden City, N Y I should like to ask Dr Ivy whether he has used this test in the equivocal case, roentgenologically speaking, whether it has been possible to establish the presence of ulcer or rule out the presence of ulcer on the basis of an evasive or equivocal x-ray finding.

DR HEINRICH NECHELES, Chicago Caffeine has been used for stomach tests a long time in Europe. I wonder why it has not found wider application. Starkenstein has shown why ulcer patients should drink their coffee with cream or milk, because with the latter substances the toxicity of caffeine is actually lowered. Apparently a slower absorbed and less toxic compound is formed between lipid and caffeine. Rats injected with a minimal toxic dose of caffeine or black coffee died in a short time. They lived when the same amount of caffeine or of black coffee was mixed with milk or with cream.

DR A C IVY, Chicago In regard to the equivocal case so far we have had experience with only 1 patient who had hematemesis for some obscure reason. No niche or disturbance could be found on x-ray examination. The patient gave the typical caffeine curve of duodenal ulcer. I have forgotten whether or not an operation was done, but we thought that the hemorrhage was due to bleeding from superficial lesions of the gastric mucosa. In regard to the literature cited by Dr Necheles, that literature is covered in our complete manuscript and could not be reviewed in the time allowed.

THE EFFECT OF PENICILLIN ON RHEUMATOID ARTHRITIS

MAJOR EDWARD W BOLAND

CAPTAIN NATHAN E HEADLEY

AND

LIEUTENANT COLONEL PHILIP S HENCH

MEDICAL CORPS, ARMY OF THE UNITED STATES

The cause of rheumatoid (atrophic) arthritis is unknown. Of the many impressions regarding its cause the microbic hypothesis is still the most widely accepted and, of the many different bacteria which have been incriminated, hemolytic streptococci have been since 1929, most under suspicion.¹

Hemolytic streptococci from time to time have been recovered from the synovial fluid and blood, from foci of infection and occasionally from synovial membrane, bone and lymph nodes of patients with rheumatoid arthritis. The blood of the majority of patients who have this disease contains antibodies against hemolytic streptococci, that is, agglutinins, generally in high titer and precipitins for the C substance of hemolytic streptococci. Although the concentration of antistreptolysins and antifibrinolysins in the blood is not increased except in some early or acute cases, the skin of patients with rheumatoid arthritis often is found to be hypersensitive to extracts of hemolytic streptococci.

Such is the direct and indirect evidence on which the argument against hemolytic streptococci has been based. But since many patients with unmistakable rheumatoid arthritis do not present such evidence, the hypothesis has remained presumptive only.

Ever since it was announced that penicillin was extremely effective against a variety of infectious agents including hemolytic streptococci many physicians and a host of rheumatic patients have been hopefully awaiting news that penicillin might prove effective against rheumatoid arthritis. True, the sulfonamides, also effective against hemolytic streptococci, have proved useless against this disease.² But it was hoped that penicillin might somehow prove to have power superior to sulfonamides against hemolytic streptococci or, if hemolytic streptococci were not the cause of rheumatoid arthritis, perhaps penicillin might kill the 'undiscovered germ' of the disease. Hence even though we never had accepted hemolytic streptococci as the cause,¹ we were pleased when the War Department and the Surgeon General's Office authorized the staff of the Rheumatism Center of the Army, at the Army and Navy General Hospital,³ to give penicillin a clinical trial in rheumatoid arthritis.

PLAN OF INVESTIGATION

Two chief policies governed our investigation.

Policy Regarding Selection of Cases—The only cases chosen for trial of treatment with penicillin were those in which the disease had advanced far enough to be diagnostically unmistakable but not far enough to have produced irreversible changes (destruction of cartilage

Lieutenant Colonel Hench is on leave of absence from the Division of Medicine, Mayo Clinic, Rochester, Minn.

From the Rheumatism Center of the United States Army, Army and Navy General Hospital, Hot Springs, Ark.

3 Hench P S and Boland E W Unpublished data

and subchondral bone notable flexion deformities) the presence of which might have made difficult a clearcut evaluation of results

Policy Regarding Dosage—We decided to give penicillin long enough and in large enough doses so that were our results negative, it could not well be said that our patients had not received sufficient amounts of the material

PATIENTS TREATED

Ten patients have been treated intensively (table 1) All were male soldiers recently on active duty Their ages were from 23 to 45 (average 30) years

Duration of Illness—Eight of the patients never had had the disease prior to active duty Two of the patients had had the disease mildly in civilian life One of these 2 (patient 7) had had three interrupted periods of mild arthritis between 1930 and 1934 then none until 1943, the other (patient 10) had had mild periodic sacroiliac backache since 1938, but the periph-

ingers, thickened, tender metatarsals swollen toes ankles wrists, knees and so forth In 6 cases definite effusion was present in the knees There were early slight flexion deformities of the knees in 4 cases and of the elbows in 2 cases Several patients exhibited mild but definite muscular atrophy Therefore the activity of the disease was graded 2 to 2 plus (table 1)

Roentgenograms—In no case were there as yet any notable roentgenographic alterations in the joints, such as definite thinning of joint spaces or irregularities in bony contour Present in some joints were increases in periarthritic shadows and evidence of slight atrophy of bone

Laboratory Data—Sedimentation rates were determined by the Wintrobe method (normal values 0 to 9 mm per hour) Rates were increased in every case (table 1) Of the 10 patients 4 had slight secondary anemia (hemoglobin 11 to 12.5 Gm per hundred cubic centimeters) and 1 had moderate anemia (hemoglobin

* Grade 1 would indicate the least and grade 4 the greatest activity

eral joints had been affected only in the past thirteen months Excluding the disease from which these 2 patients had suffered before they entered military service, the 10 patients had been ill from two to eighteen months, an average of 7.4 months Thus, their disease was in a fairly early stage

Symptoms—The symptoms were characteristic of rheumatoid arthritis aching soreness stiffness and "jelling" of joints and muscles, weakness fatigue malaise, loss of appetite, some loss of weight and hyperhidrosis of the extremities Five of the patients walked with a limp, 1 was temporarily bedridden Before they had come to this hospital the patients had been treated with salicylates, rest vitamins sulfonamides (no effect) and the removal of tonsils (2 cases) and teeth

Examination of Joints—Despite its relatively short duration, the disease had been decidedly progressive such that in every case several or many joints were involved Extension of the disease therefore was graded 2 and 3 on a scale in which 1 would indicate the least and 4 the greatest extension (table 1) The joints presented the classic picture of advancing rheumatoid arthritis symmetrical fusiform swelling of the

9.5 Gm per hundred cubic centimeters) Blood cultures, made in every case were negative Cultures and smears for bacteria in the synovial fluid were made in 6 of the 10 cases and in all results were negative Agglutinations for brucellosis and serologic tests for syphilis gave negative results in the 10 cases In 4 of the 10 cases leukocyte counts were made of the synovial fluid (table 2)

7	5 000	8 700
10	44 000	28 700

DOSES OF PENICILLIN

In the treatment of other diseases the following doses of penicillin generally have been considered adequate for severe acute infections with hemolytic streptococci or *Staphylococcus aureus* about 120 000 to 240 000 Oxford units daily for ten to fourteen days, the total dose being from 500 000 to 1 000 000 or more units for severe chronic infections such as osteomyelitis and

compound infected fractures, about 120,000 Oxford units daily.⁴ Recent reports have indicated that doses somewhat smaller than those mentioned are generally effective for severe infections with or without bacteremia, 48,000 to 160,000 Oxford units daily for chronic infections 60,000 or more Oxford units daily. Indeed one experienced investigator (Herrell) has stated that a daily dose of from 40,000 to 60,000 (occasionally 100,000) Oxford units is entirely adequate even for severe infections.

In the light of the foregoing and in view of our policy of giving doses that might be considered more than sufficient rather than too low, we administered penicillin as follows. The first 2 patients received 320,000 units daily for the first five days then 160,000 units daily for the next ten days. In addition, the second patient received 25,000 units intra-articularly (into a knee) on two successive days, making the total dose in the first 2 cases respectively 3,200,000 and 3,250,000 Oxford units over a period of fifteen days.

In view of the negative results in these first 2 cases, it was decided to treat the next 2 patients daily for one month if possible. They were given daily doses of 160,000 units but, at the end of twenty days it seemed wise to stop the injections since no results were apparent and the patients were becoming "needle shy." Thus in case 3 as well as in case 4 a total of 3,200,000 units was given over a period of twenty days.

In the remaining 6 cases the doses were 240,000 units for the first day and 120,000 units daily thereafter for thirteen more days, a total of 1,800,000 units for each patient within fourteen days.

In each case the penicillin was given intramuscularly in divided doses one dose every three hours day and night (table 1).

RESULTS

To evaluate our results critically we used a modification of a special research examination chart described elsewhere.⁵ Every so often (before, during and after treatment) notations were carefully made as to articular swelling and tenderness, pain at rest, pain on voluntary and on forced motion of joints, limitation of motion and size of joints (measured with tape). Each examination sheet was filed away and was not studied until the courses of treatment had been concluded. In this way we were not influenced by the previous examinations.

Results from penicillin were essentially negative (table 1). We cannot even report the "inevitable 75 per cent of cases improved," as is reported so frequently after a wide variety of treatments. Throughout the course of treatment minor fluctuations in some of the articular characteristics were noted as can be expected even in cases of rheumatoid arthritis in which treatment is not given. But in general what few changes occurred were insignificant.

Joints—In 7 cases there was no significant objective or subjective improvement. One patient felt worse after two weeks of treatment. In 1 case (case 6) there was slight subjective but no definite objective improvement. In 1 case (case 8) there was moderate objective and subjective improvement during the two weeks of treatment, that is slight but definite reduction of pain and tenderness of fingers and ankles. But the condition of the metatarsophalangeal joints was not definitely improved, the sedimentation rate had increased slightly, and the patient was by no means cured or even much improved in condition. In view of the capricious nature of rheumatoid arthritis the improvement in this case must be regarded as unrelated to the penicillin.

Laboratory Data—The sedimentation rates recorded in table 1 are the average of three contiguous (and almost similar) determinations made before treatment and two made after treatment. In no case were there changes in the rate which could not be explained on the basis of variations inherent in the test itself or of the minor fluctuations of the disease.

Leukocyte counts made on synovial fluid after treatment did not differ materially from those made before treatment (table 2).

General—Six of the 10 patients noted definite improvement in appetite in the course of treatment. In 4 the increased appetite was sustained after discontinuance of administration of penicillin. It is problematic whether this improvement was a side effect from penicillin or the result of rest and diet in the hospital.

TOXIC REACTIONS

Fever, chills, urticaria or other toxic reactions did not develop in any of the cases. The only unpleasant feature noted was the transitory mild to moderate intramuscular soreness at the sites of injection, for this no special applications were necessary.

SUMMARY AND CONCLUSIONS

1. Penicillin was given to 10 soldiers with early but progressive rheumatoid arthritis.

2. Large doses of penicillin were given intramuscularly every three hours day and night. The daily doses of penicillin were from 120,000 to 320,000 Oxford units; total doses were from 1,800,000 to 3,250,000 units within fourteen to twenty days. Such large doses are known to be adequate, indeed perhaps more than adequate, against even severe infections (with or without bacteremia) from hemolytic streptococci, *Staphylococcus aureus* and so forth.

3. Our clinical results from penicillin given in the doses stated over a period of fourteen to twenty days were essentially negative. In 7 of the 10 cases there was no significant subjective or objective improvement. One patient felt worse but did not appear to be in worse condition than before treatment. In 1 case there was slight subjective, but no definite objective improvement. One patient experienced moderate objective and subjective improvement in some but not in all his affected joints; the sedimentation rate increased slightly during treatment and he was by no means cured or even decidedly improved. In view of the capricious nature of rheumatoid arthritis the improvement in these 2 cases must be regarded as unrelated to the penicillin.

4. There was no definite evidence of improvement as measured by laboratory tests. There was no significant improvement in sedimentation rates or in the

comparative leukocyte counts on synovial fluid, made before and after treatment

5-Definite improvement in appetite was noted by 6 of the 10 patients. It may have been unrelated to treatment with penicillin or it may have been a general side effect thereof

6 Our results offer no support to the idea that hemolytic streptococci may be etiologically related to rheumatoid arthritis

7 In view of these negative results with rather large doses of penicillin, it does not seem unreasonable to assume that rheumatoid arthritis is not caused by any of the bacteria which are already known to be rapidly affected by penicillin

8 From these negative results we would conclude that penicillin probably should not be used for the further clinical treatment of rheumatoid arthritis, at least until the material is available in something approaching inexhaustible quantities. Further researches with penicillin in rheumatoid arthritis may be in order. At present the limited supplies available for clinical use should be allotted for the treatment of patients with diseases in which curative results are more likely to eventuate than in rheumatoid arthritis

THE EFFECT OF VITAMIN SUPPLEMENTS ON NORMAL PERSONS

JULIAN M. RUFFIN, MD

AND

DAVID CAYER, MD

DURHAM, N. C.

At the present time the use of vitamins is widespread throughout the country, not only in the treatment of disease, but also by apparently normal persons. While no one would question the employment of vitamin therapy in frank deficiency diseases or even in suspected deficiency states, still one wonders if the indiscriminate use of vitamins, sold over the counter to people who have no obvious disease, is justified. It has been argued that such vague symptoms as weakness, nervousness, fatigability and insomnia can result from a vitamin deficiency and therefore, when such symptoms appear, vitamin therapy should be instituted¹. Recent surveys, with the recommended daily allowances of the National Research Council as a guide, have indicated that the average American diet often is not adequate to maintain optimal nutrition. This has been used as an additional argument for the administration of vitamins to people without obvious disease on the assumption that they may actually have a "subclinical deficiency" of which they are not aware². It has been implied that even when no demonstrable deficiency exists, one's sense of well-being and ability to perform work can be improved greatly by the addition of vitamins to the diet. As pointed out by the Councils on Food and Nutrition and on Industrial Health there is at present no conclusive evidence to substantiate this point of view³. In an

effort to determine the effect, if any, of various vitamin supplements on apparently normal persons, the following study was undertaken

METHOD

Volunteer medical students and technicians were used as subjects. They all continued their usual activities and ate essentially the same diet. Each subject was

TABLE 1—Supplements for Each Group

Group A—Vitamin tablets	3 per day
Liver extract tablets	6 per day
Group B—Vitamin tablets	3 per day
Yeast extract tablets	6 per day
Group C—Vitamin tablets	3 per day
Placebos	6 per day
Group D—Vitamin tablets	3 per day
Group E—Placebos	6 per day

given a work sheet to be kept daily and was instructed to record his impression as to the effect of the medication he was taking on the appetite, energy and pep, general health, "gas" or indigestion, nausea, vomiting, the number of stools per day, abdominal pain and weight. Extraneous factors which might possibly have affected the subject also were noted. A code was printed on the work sheet to insure uniformity of recording. The time of the experiment was purposely placed in the midterm to avoid the factor of examinations. The duration was one month during which each subject took his supplements daily. No subject knew what he was receiving or to what group he belonged. At the beginning of the experiment they were told that one group would receive placebos and the remainder various vitamins. They were instructed not to compare notes or discuss their symptoms with fellow subjects.

Two hundred subjects were selected and divided into five groups. The supplements for each group were shown in table 1. The supplements used were of the same size and appearance, so that identification was difficult, if not impossible without chemical analysis.

The contents of the various supplements were

Vitamin tablets 5 vitamin A 2500 U S P units vitamin D, 200 U S P units thiamine hydrochloride, 1 mg riboflavin 15 mg ascorbic acid, 27.5 mg nicotinamide 10 mg
Liver extract tablets 0.5 Gm of Wilson's liver extract 1 20
Yeast extract tablets 0.5 Gm of dried yeast extract
Placebos dextrose

TABLE 2—Appetite

Supplement	Group A Vitamins and Liver Extract	Group B Vitamins and Yeast	Group C Vitamins and Placebos	Group D Vitamins	Group E Placebos
Improved	6	3	9	5	3
Unchanged	11	2	24	5	29
Decreased	0	3	2	2	1
Total	17	38	35	32	33

The coating of the tablets was gelatin cane sugar with iron oxide as a coloring matter.

Reliable data were obtained from 182 subjects the number in each group being shown in the accompanying tables.

Appetite—The appetite was indicated as improved, unchanged or decreased. The subject was classified as having an improvement or impairment of appetite only

The vitamin tablets were the usual government issue and furnished by the Office of the Quartermaster General. The remainder of the supplement were furnished through the courtesy of the Vitco Products Company, Chicago.

From the Department of Medicine, Duke University School of Medicine.

This study was conducted at the request of the Office of the Quartermaster General, U. S. Army.

Present	—	1	1	1	0
Absent	1	32	31	—	30
Total	1	33	32	1	30

results are shown in tables 6 and 7. No significant differences were noted in the symptoms "gas and indigestion" by the various groups. However in the group taking yeast there was a definite increase in the number of subjects who recorded the development of abdominal pain.

Nausea, Vomiting and Diarrhea—Except for 1 subject taking placebos nausea and vomiting occurred only in those taking liver extract and yeast particularly

the liver extract. Likewise diarrhea developed most frequently in those taking liver and yeast (tables 8 and 9).

STATISTICAL ANALYSIS

A statistical analysis of the data was made using the chi square test.⁶ In analyzing the effects of the supplements in the five respective groups, only six comparisons indicated real or significant differences. These were noted in nausea and vomiting, abdominal pain and diarrhea. A significant increase in diarrhea and a highly significant increase in abdominal pain and in nausea and vomiting occurred in those groups receiving liver extract and yeast. No significant difference was noted in appetite, energy and "pep," "gas" and indigestion, general health or weight among the various groups.

COMMENT

Our purpose in this study was to obtain impartial and intelligent daily records of the effect of various vitamin supplements on apparently normal persons. It was felt that in such a study medical students would be not only cooperative but critical as well. The duration of the experiment was set arbitrarily at thirty days. In our experience patients having frank deficiencies recover rapidly when specific therapy is instituted. It is reasonable to assume that a subclinical deficiency should respond just as promptly to treatment and therefore it was felt that nothing would be gained by prolonging the experiment.

All of the subjects were consuming the usual American diet and apparently were in good health. Before beginning the experiment 20 of them selected at random had vitamin studies made, including the determination of carotene, vitamins A and C, nicotinic acid, thiamine hydrochloride, riboflavin, pyridoxine, pantothenic acid and prothrombin time. All of these were within normal limits.

⁶ The Office of the Quartermaster General prepared this statistical study.

The selection of appetite energy and pep' and general health for evaluation was based on the assertion that vitamins will stimulate the appetite, increase energy and "pep" and improve the general health even in apparently normal persons. Our own experience suggested that untoward symptoms might arise following the administration of yeast or liver extract. Therefore "gas," indigestion, nausea vomiting abdominal pain and diarrhea were included in the work sheet.

As already stated the greatest care was exercised in the evaluation of changes noted by the subject. Only when these were definite and unmistakable were they recorded as such. The evaluation of the data submitted by each subject was made without knowledge of what supplement he had been taking.

It is well known that yeast and liver extract occasionally may cause distressing gastrointestinal symptoms, and this was confirmed by the observations reported in this study. The same beneficial effect was noted on the appetite energy and "pep," general health and weight in the group taking placebos as in the groups taking the various vitamin supplements.

SUMMARY

The administration of vitamin supplements to a group of apparently normal persons, consuming the usual American diet had no demonstrable beneficial effect.

INTERSTITIAL CYSTITIS OF MEN

A REVIEW OF SEVENTY-EIGHT CASES

DAVID S. CRISTOL, M.D.

Fellow in Urology Mayo Foundation

LAURENCE F. GREENE, M.D.

Member of the Section on Urology Mayo Clinic

ROCHESTER, MINN.

AND

COMMANDER GERSHOM J. THOMPSON

MC-V(S), USNR

Ever since Hunner¹ described the clinical picture of ulcer of the bladder in women which has since borne his name, relatively few cases involving men have been described. Peterson and Hager² demonstrated the general incidence of interstitial cystitis by reporting 8 cases, all involving women from a series of 1,707 urologic patients. This group was made up of 1,292 men and 415 women. While most of the patients have been women, this disease has been observed among men by many investigators. In a series of 14 cases reported in 1922, Kretschmer³ described 1 case in a man. In 1929 Hinman⁴ reported 6 cases in men in a series of 110 cases. Two of the 15 cases that Bumpus⁵ reviewed in 1930 were in men. In 1932 Folsom⁶ described his series of 20 cases of interstitial

cystitis, 3 of which were in men. In 1935 Young⁷ reviewed 45 cases, of which 41 were in women and 4 in men. Higgins⁸ reviewed 100 cases in 1941, 6 in men.

We are presenting some observations derived from reviewing the records of 78 cases of interstitial cystitis involving men. It is interesting that from an original group of 113 cases accumulating over a period of twenty-six years in which a diagnosis of interstitial cystitis had been made, only 2 have proved subsequently to be cases of vesical neoplasm and 1 eventually proved to be a case of tuberculous cystitis. Of the original group we selected 78 cases in which we have follow-up information which corroborates the diagnosis of interstitial cystitis. The remaining 32 cases are not included in this report because we did not believe that the diagnosis of interstitial cystitis was established unequivocally.

ETIOLOGY

The causation of interstitial cystitis is still a mystery. As in many other conditions in which the etiologic agent is not definitely established, focal infection has received its share of consideration. Hunner, as well as Meisser and Bumpus,⁹ favored the hypothesis of the focal origin of this disease. However, Keene¹⁰ was unable to produce even symptomatic relief after carefully eradicating all foci of infection. Hinman made a careful search for foci of infection in the 110 cases that he reviewed. In 80 per cent of the cases induced abortions, ectopic pregnancies, pelvic inflammatory disease or pronounced menstrual irregularity had occurred. Of his 6 male patients, 3 had a positive history of gonorrhea and 1 had syphilis with a primary genital chancre. Higgins found disease of the upper part of the urinary tract, such as pyelonephritis, hydronephrosis or infected hydronephrosis, to be present in 19 per cent of 100 cases. Of the 6 men in Higgins's group, 3 had coexisting prostatitis and 1 had syphilis. Meads¹¹ considered neglected cystitis as ranking with foci of infection as an etiologic agent. Nelson and Pinard¹² stated that practically all men suffering from interstitial cystitis have pyogenic infection of the prostate and seminal vesicles. Young⁷ reported that 2 patients were completely cured after eradication of chronic prostatitis.

In our series 11 (14 per cent) men had coexisting chronic prostatitis. In 5 of the 67 cases in which the upper part of the urinary tract was investigated there were chronic inflammatory changes of the kidney and ureters. In 1 there was rather active bilateral pyelonephritis and in 2 there were small, asymptomatic renal calculi. Twenty-six patients (33 per cent) gave a positive history of previous gonorrheal infection, while 48 patients (62 per cent) denied any such history. Urethral strictures were present in 8 cases (10 per cent) and previous abdominal operations had been performed in 9 (12 per cent) of the cases.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy department.

INCIDENCE

Interstitial cystitis is predominantly a disease of women. Most authorities estimate that it is four times as common among women as among men. Our experience essentially bears out this information. Symptoms began between the ages of 20 and 59 years in 64 (82 per cent) of our 78 cases in men. We have observed that

Fig. 1—Thinned vesical epithelium and subepithelial inflammatory changes slightly reduced from a photomicrograph with a magnification of 11 diameters

in the reported cases men were generally younger at onset of symptoms than women. The earliest onset of symptoms in our series was at the age of 16 years. The oldest was at the age of 74 years.

PATHOLOGY

Specimens of the vesical wall were available for microscopic examination in 17 of our cases. These examined specimens were from the cases in which

Fig. 2—Inflammatory changes within the subepithelial connective tissue slightly reduced from a photomicrograph with a magnification of 10 diameters. Increased vascularity, collections of leukocytes and erythrocytes and varying degrees of edema.

biopsy, segmental resection or total cystectomy had been performed. A pathologist confirmed our diagnosis in each of these cases. Following is a description of the pathologic characteristics of interstitial cystitis written by Dr Broders.¹³

13 Dr Broders is head of the Section on Surgical Pathology in the Mayo Clinic and professor of pathology in the Mayo Foundation Graduate School, University of Minnesota.

Little can be added to Hunner's description of the pathologic process in the urinary bladder variously designated "Hunner's ulcer," "submucous ulcer," "elusive ulcer," "paracystitis," "panmural ulcerative cystitis" and "chronic interstitial cystitis." The process is an inflammation of the connective tissue of the bladder that is by far most pronounced and apparently primary in the subepithelial connective tissue. This layer consists of the connective tissue of the mucosa and the so-called submucosa and it lies between the epithelium and the musculature. The inflammatory process extends to the epithelium, intermuscular connective tissue, musculature, serosa or adventitia.

When the lesion is removed and examined, the inflammation is found to be in a chronic state. However, it would be contrary to sound reasoning to assume that the inflammation is chronic from the outset. It seems reasonable to assume, therefore, that the inflammatory process passes through acute, subacute and chronic phases and that there are exacerbations of acute and subacute phases which tend to intensify the chronic phase.

The involved portion of the wall of the bladder is thickened; however, the epithelial layer is for the most part thinned (fig 1) so that areas exist in which the epithelium is only one or two cell-layers thick and in other areas the epithelium is destroyed and superficial ulceration remains.

Fig. 3—Collections of inflammatory cells within the intermuscular connective tissue slightly reduced from a photomicrograph with a magnification of 80 diameters.

In the subepithelial connective tissue where the inflammation is most pronounced the characteristics are as follows: increased vascularity, numerous lymphocytes, mostly small lymphocytes, a fair number of polymorphonuclear leukocytes both within and without the blood and lymph vessels and spaces, a few monocytes and plasma cells, numerous erythrocytes within and without the blood vessels and blood spaces, and varying degrees of edema (fig 2). In other words, the process is comparable to that found in the inflammatory granulating base of a chronic excavated ulcer of the urinary bladder or stomach.

The inflammatory process in the intermuscular connective tissue (fig 3), musculature, serosa or adventitia is less pronounced than that in the subepithelial connective tissue. The serosa or adventitia is usually thickened. The musculature may be distorted to some extent, however, there is very little loss of continuity of the musculature in contrast to the marked loss of continuity found in an excavated ulcer of the bladder or stomach.

In some lesions there is very little increase of fibrous connective tissue, while in others the increase is so marked as to produce real fibrosis throughout the vesical wall with or without hyaline degeneration. The amount of fibrosis is probably in direct proportion to the duration of the inflammatory process. The process as a whole resembles closely that relatively rare lesion of the stomach known as "limitis plastica" of non-neoplastic type.

SYMPTOMS

The most distressing symptoms of interstitial cystitis are highly characteristic regardless of the sex. Most prominent is "clocklike" urinary frequency with urgent voidings approximately every two hours during day and night. Almost equally distressing and universal is lower abdominal suprapubic or perineal pain relieved by voiding small amounts of urine and aggravated by jarring or overdistention of the bladder. These symptoms predominated in our series. Hematuria noted prior to treatment or examination occurs fairly often and has been noted in 18 per cent of Higgins's⁵ series, in 13 of Krietschmer's,³ 44 reviewed cases and in 20 per cent of the cases reviewed by Smith and Conroy.¹⁴

In our series 24 patients (31 per cent) gave a history of terminal gross hematuria. Burning urgency and vesical tenesmus were occasional complaints. Obstructive urinary symptoms of varying degrees were present in 14 (18 per cent) of our cases. While one would expect obstructive urinary symptoms to affect some of any such group of male patients, it is interesting that in several cases after a transurethral prostatic operation had been performed the obstructive symptoms persisted and were relieved only after the interstitial cystitis had been discovered and treated. The report of case 2 illustrates this point. It is also interesting that obstructive symptoms have been observed among women.

DIAGNOSIS

The diagnosis of interstitial cystitis is established by the patient's characteristic history together with rather typical cystoscopic findings. The more important findings include reduction of vesical capacity, ideally a urine free from pus, blood or organisms unless the patient has had previous treatment or accompanying urologic pathologic changes, and a rather typical cystoscopic appearance of the bladder which will vary to a great extent depending on the degree of healing present. The most characteristic cystoscopic finding is one or more discrete salmon pink, shrimp or Russian dressing colored areas found mostly on the apex or dome but frequently on any area of the bladder except the trigone. Instrumental palpation of these areas will produce the identical pain that the patient has described in the case history. Overdistention of the bladder produces a linear splitting with associated hemorrhages of the mucosa overlying these areas. Finally, most patients will obtain symptomatic relief from overdistention of the bladder by lavage with increasing concentrations of silver nitrate fulguration of the involved mucosa or a combination of these procedures. Cases in which essentially all of these features were observed we regarded as typical. Cases in which other urinary complaints were recorded or in which these findings were lacking we arbitrarily considered as being atypical. We insisted on all the cystoscopic findings for the diagnosis, and in every case the opinion of at least two cystoscopists was obtained.

The data in 64 (82 per cent) of the 78 cases were typical, while the data in the remaining cases were considered as being atypical because of additional obstructive symptoms. In only 16 (21 per cent) of our cases was the urine free from pus, blood and organisms. It is interesting to note that in these cases there had been no previous cystoscopy or treatment. In 37 cases

(47 per cent) 0 to 15 pus cells per high power field were observed in the initial examination of the urine while in 34 cases (44 per cent) 15 to 40 pus cells were observed which were negative to Gram's stain. Positivity to Gram's stain and positive culture of the urine were present in 7 cases (9 per cent). Of the latter group there were 3 cases in which *Escherichia coli* was cultured, 2 cases in which *Pseudomonas* was cultured and 2 cases in which *Streptococcus fecalis* was cultured. In 1 of the cases in which *Escherichia coli* was cultured gram-negative bacilli were recovered from both kidneys and the disease in this case was considered to be active bilateral pyelonephritis with interstitial cystitis. As had been pointed out by Hinman,⁴ Higgins⁵ and others the high percentage of patients suffering from pyuria can be attributed to previous treatment and instrumentation.

Interstitial cystitis in both sexes is to be distinguished from so-called simple ulceration, tuberculous ulceration, the accompanying inflammation of an underlying neoplasm and mucosal lesions resulting from extravescical lesions and among women, from ulceration following application of radium to the cervix or vagina. We considered it necessary to exclude tuberculosis in 67 (86 per cent) of the cases.

TREATMENT

We have relied chiefly on vesical overdistention or on instillation into the bladder of increasing concentrations of silver nitrate. The former method is usually selected in cases of severe interstitial cystitis in which prompt relief is desired. It is our impression that overdistention with the patient under local anesthesia is useless; this procedure requires either intravenous or spinal anesthesia. Our method of vesical overdistention consists in distending the bladder under vision until actual splitting of the mucosa which overlies the region or regions of interstitial cystitis is noted. During the process the affected regions are kept under constant inspection and the first evidence that "splitting" is about to occur is a bluish white discoloration of the mucosa. Actual splitting occurs shortly thereafter and is followed by bleeding from the site of rupture. The amount of fluid necessary to produce splitting varies from 200 to 800 cc and the procedure can be repeated safely at intervals. Usually, superficial fulguration of the regions of interstitial cystitis is carried out. At times overdistention is supplemented by the use of continuous vesical lavage with increasing concentrations of silver nitrate.

Dramatic results may be obtained by the use of silver nitrate. The method we employ consists in the instillation of 1 to 2 ounces (30 to 60 cc) of solution of silver nitrate into the bladder daily. At the outset a 1:3,000 solution is employed, and the concentration is increased gradually until 1 per cent solution of silver nitrate can be tolerated. The solution is instilled into the bladder by means of a catheter, allowed to remain in place for five minutes and then drained off through the catheter. We do not employ any local anesthetic agents although it may be necessary to prescribe codeine or belladonna and opium suppositories if the treatment results in unusual pain. When the proper concentration has been reached and the patient is comfortable, it may be possible to keep him in that condition by the monthly or bimonthly instillation of 1:1,000 or 1:2,000 solution of silver nitrate. Segmental resection, subtotal cystec-

tom presacral neurectomy and the instillation of mild protein silver, phenol or alcohol are mentioned simply for the sake of completeness

REPORT OF CASES

In the reports of the cases which follow, the first illustrates a rather typical case. The second illustrates the fact that obstructive urinary symptoms which were not relieved by a prostatic operation were relieved by treatment of the interstitial cystitis.

CASE 1—A white man aged 35, a school teacher, registered at the Mayo Clinic on Dec. 27, 1933 complaining of day and night urinary frequency associated with an aching discomfort in the bladder and urethra. These symptoms first had begun three years before and had been becoming constantly more severe. In February 1932 cystoscopy had been performed and the patient had been told that he suffered from interstitial cystitis. A left pyelogram was made at the same time and no abnormalities were noted. Tuberculosis had been excluded by acid fast stains and inoculations of guinea pigs. Vesical overdistention and lavage had been performed repeatedly without improvement. One physician had found that the patient had prostatitis and administered many prostatic massages, which did not affect the patient's symptoms. On the recommendation of his physician his tonsils were removed. The patient's history by symptoms as well as his family history was noncontributory. His past medical history was also of no significance and he stated that he had never had gonorrhea.

The results of general physical examination were essentially negative. Urinalysis revealed 7 pus cells per high power field of the microscope. The erythrocyte count, the leukocyte count and the value for hemoglobin were within normal limits. The prostatic secretion appeared normal. Results of the flocculation test for syphilis and roentgenograms of the thorax and pelvis were all negative. Cystoscopy with the patient under pentothal sodium anesthesia revealed an area of interstitial cystitis involving the posterior wall and extending up to the dome. The vesical capacity was 150 cc. The bladder was overdistended with 475 cc of water to produce splitting of the mucosa over the involved areas. Vesical overdistention was repeated twice more at six day intervals and the patient was given vesical lavage was instructed to follow a ketogenic diet and was dismissed with only moderate relief of symptoms.

The patient returned to the clinic on Feb. 15, 1939 with symptoms similar to those at the time of his first visit after having been free from symptoms in the intervening six years. Cystoscopy performed the next day with the patient under pentothal sodium anesthesia disclosed a typical region of interstitial cystitis on the left wall of the bladder measuring approximately 3 cm in diameter and another on the right lateral wall measuring approximately 2 cm in diameter. The bladder was overdistended to 225 cc with characteristic splitting and hemorrhage in both regions. Specimens taken at this time for biopsy were reported as being inflammatory tissue. The patient was given a course of emetine and instructions were sent to his local physician for administering the second course of treatment.

The patient returned on Aug. 27, 1940 complaining of a return of the original symptoms after sixteen months of considerable improvement. Since he could not remain here he was referred to his local urologist for overdistentions of his bladder to be performed at intervals.

CASE 2—A white man aged 42 presented himself at the clinic on Sept. 23, 1942 complaining of periodic dysuria, urinary frequency, nocturia and perineal pain that had begun in 1932. These symptoms had progressed and become more severe so that by April 1942 he was voiding small amounts of urine every hour during the day and six times during the night suffering from considerable dysuria and perineal pain and experiencing hesitancy with narrowing of the urinary stream. He consulted a urologist in his home town and transurethral prostatic resection was performed in April 1942. His post-operative course was uneventful but his symptoms were unaffected. Since that time his home physician had been giving him vesical lavages and urethral dilations. The patient had

suffered a definite attack of gonorrhea seventeen years and a questionable attack of gonorrhea seven years before. Appendectomy had been performed in 1927.

Results of general physical examination were essentially negative. Urinalysis revealed 4 pus cells and an occasional erythrocyte per high power field of the microscope. A culture of the urine was negative. There was 20 cc of residual urine. The erythrocyte count, leukocyte count and value for hemoglobin were within normal limits. Results of the flocculation test for syphilis were negative. The blood urea was 26 mg per hundred cubic centimeters of blood. Roentgenograms of the thorax and colon did not reveal any abnormalities. The prostatic secretion was normal. An excretory urogram was negative. Cystoscopy performed with the patient under intra-venous pentothal sodium anesthesia disclosed a typical region of interstitial cystitis on the dome of the bladder just anterior to the air bubble. The prostatic urethra and the vesical neck appeared normal. The bladder was overdistended to 425 cc resulting in bleeding and rupture of the mucosa at the site of the region of cystitis. A course of lavage of the bladder with silver nitrate was given. By Oct. 12, 1942 the patient was voiding a good stream without dysuria and his nocturia was reduced 50 per cent.

The patient returned to the clinic on April 14, 1943 complaining of a recurrence of his urinary symptoms but to a less severe degree than formerly. The results of physical examination and the laboratory findings were similar to those of the earlier admission. Repeated examinations of his urine for the tubercle bacillus were negative. On April 19, 1943 cystoscopy was done with the patient under intravenous pentothal sodium anesthesia and a region of interstitial cystitis was found in the right side of the dome. This region was seen to have torn and bled after the bladder had been overdistended with 600 cc of water and was then lightly fulgurated. Symptomatic improvement was almost immediate and the patient was given a further course of lavage with silver nitrate. The patient requested and was granted another overdistention of the bladder. He was dismissed as greatly improved on May 13, 1943. The patient wrote to us on Aug. 30, 1943 and stated that he was feeling entirely well.

SUMMARY AND CONCLUSIONS

On the basis of a review of data on 78 cases of interstitial cystitis of men the following conclusions are drawn:

1. Although interstitial cystitis is predominantly a disease of women it is found to have a significant incidence among men. A search for evidence of interstitial cystitis among male patients will explain a number of cases of puzzling and intractable cystitis.

2. The clinical picture among male patients is often deceiving because of accompanying obstructive symptoms especially in the prostatic age group.

3. Still more deceiving are the cases in which obstructive symptoms are superimposed without any obstructive pathologic change. In these cases the obstructive symptoms are part of the picture of cystitis and will be found to be relieved by treatment of the cystitis rather than by a prostatic operation.

A Great Figure in Syphilology—Phillipe Ricord (1800-1889) is one of the great figures in syphilology. He was an investigator of the first rank and he is another illustration of the men who have been most fruitful in original scientific work while carrying the burdens of an enormous practice. He rose from poverty to large wealth and became one of the most popular and influential citizens of Paris. He was born in Baltimore and until he was 20 lived in the United States, but the only claim the United States can make upon him is that it gave his father's family refuge in time of revolution and afforded him an opportunity to get his preliminary education and to study natural history under his uncle—Pusey, William Allen. *The History of Dermatology*, Springfield, Ill., Charles C. Thomas, 1933.

TRANSIENT HYPERTENSION

ITS SIGNIFICANCE IN TERMS OF LATER DEVELOPMENT OF SUSTAINED HYPERTENSION AND CARDIOVASCULAR-RENAL DISEASES

ROBERT L. LEVY, MD

NEW YORK

BRIGADIER GENERAL CHARLES C. HILLMAN

UNITED STATES ARMY

WILLIAM D. STROUD, MD

PHILADELPHIA

AND

PAUL D. WHITE, MD

BOSTON

For many years the significance of transient hypertension has been a topic of discussion. As long ago as 1921 Fahrenkamp¹ and Kylan² independently noted that excessive variability of the blood pressure, with temporary rises above the usual normal, sometimes was found in the early stages of hypertensive vascular disease. A little later Fahrenkamp³ stressed the importance of psychic disturbances as a cause of such vasomotor instability. More recently, numerous authors have presented data in support of the view that transient elevations of blood pressure, induced by emotion or some other stimulus, should be regarded as evidence of a possible prehypertensive state.⁴ But the number of cases studied has been relatively small, the periods of observation usually have not been long and no records have been kept between their beginning and end. Inferences drawn from insurance statistics are based almost entirely on mortality experience following a single reading and so have a limited value.

In examinations of registrants for military service transient hypertension, presumably due to nervousness, has been commonly encountered and examiners have varied in their judgment as to its importance.⁵ Mobilization Regulations prescribe that if the blood pressure appears to be abnormally high it is to be measured after the subject has rested in the recumbent position. The decision as to the acceptability of the selectee is

left to the physician who is permitted to disregard a persistent pressure of over 150 mm of mercury systolic or over 90 diastolic if, in his opinion, the rise is due to psychic reaction and is not secondary to renal or other systemic disease. It is our purpose in this study to inquire into the validity of these criteria by critical analysis of the medical records of 22,741 army officers. In the course of the discussion facts believed to apply to the general male population of comparable physical fitness and similar age groups will become evident.

MATERIAL, DEFINITIONS AND PROCEDURE

In a previous paper⁶ were described the sources of the 22,741 records on which this analysis is based, the general character of the material and the scheme followed in preparing it for study. The manner in which the blood pressures were taken and the points at which systolic and diastolic levels were measured is not known. Errors and variations in either direction were probably not great, and it is fair to assume that in such a large series of readings they canceled one another.

Definition of the terms employed is necessary for clear understanding. By transient hypertension is meant a reading of over 150 mm of mercury systolic or 90 diastolic which is followed, on any particular examination or at a later examination by a reading below these levels. The highest systolic and diastolic readings obtained in any one of a series made at a given examination were recorded. Sustained hypertension is taken to mean a reading of over 150 systolic or over 90 diastolic persisting throughout an examination and not followed in subsequent examinations by lower levels. A persistent elevation of either systolic or diastolic pressure on a final examination, even though this marked its first appearance, is considered to represent sustained hypertension.

Cardiovascular-renal diseases were grouped and included those conditions due to vascular degeneration which involved brain, heart or kidneys. Cerebral hemorrhage and thrombosis, hypertension the various manifestations of coronary heart disease and chronic nephritis and uremia were the most frequent diagnoses. Rheumatic heart disease, bacterial endocarditis, syphilitic aortitis and disturbances due to thyrotoxicosis were excluded. In the tables dealing with disability retirement and death rates, both primary (basic) and secondary (immediate) causes were included. In other words the presence of a cardiovascular-renal condition always was recorded, even though it was not directly responsible for retirement or death.

The group of neuropsychiatric disorders comprised chiefly psychoneuroses, psychoses (including the psychosis due to alcohol), manic depressive psychosis, dementia precox and mental disturbances due to cerebral arteriosclerosis (these patients often were classed merely as "mentally unsound"), it included deaths due to suicide. A few cases of tabes dorsalis and dementia paralytica were not placed in this category but were listed under the diagnosis of syphilis.

In dealing with data of this sort, age is of fundamental importance and in each table the figures are given according to age groups. The actuarial summaries (tables 7 and 8) are of necessity based on cumulative figures derived from these groups. In order to

This is the second in a series of papers dealing with 'Studies of Blood Pressure in Army Officers'

The work described in this paper was done under a contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and Columbia University.

Dr. John W. Fertig, professor of biostatistics, Columbia University College of Physicians and Surgeons, aided in the analysis and preparation of the material for final presentation.

demonstrate the influence of transient hypertension on the subsequent state of health and the cause of death, it was necessary to select, for correlation certain specific indexes. Those chosen for the purpose were the later development of sustained hypertension and the disability retirement and death rates for cardiovascular-renal diseases.

RESULTS

First Occurrence of Transient Hypertension by Age (table 1)—In this table are included only cases observed throughout each five year period. Those entering the study or dropping out during a given period were eliminated because it was impossible to know whether they had developed transient hypertension during those five years. There are two noteworthy features of this table—first that transient hypertension appears not uncommonly in the younger groups and second that the frequency with which it is first noted

TABLE 1—First Occurrence of Transient Hypertension by Age

Age	Number Under Observation Throughout Each Age Period	Number Showing First Transient Hypertension	Frequency per Cent
25-29	5,090	178	5.9
30-34	4,407	396	9.0
35-39	5,357	577	10.4
40-44	5,150	654	12.7
45-49	3,475	552	16.2
50-54	2,101	392	18.6
55-59	981	183	18.6

TABLE 2—Late Occurrence of Sustained Hypertension, by Age in Those With and Without Transient Hypertension

Age	Person Years Observed		Number Developing Sustained Hypertension		Rate per Thousand		Ratio
	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	
25-29	2,171	1,072	11	14	2.4	0.5	4.8
30-34	4,401	4,670	31	30	2.5	0.9	2.8
35-39	7,261	5,718	41	50	5.6	1.7	3.3
40-44	9,799	1,701	110	51	11.1	2.4	4.1
45-49	10,381	5,705	230	111	22.0	9.7	2.3
50-54	8,218	1,736	213	13	35.2	9.7	3.4
55-59	5,768	1,005	253	9	48.0	14.9	3.2

increases with age. The curve of increase is a smooth one beginning with 5.9 per cent in the age group 25 to 29 and reaching a plateau of 18.6 per cent at 50 to 54.

In this table and in the tables which follow, no figures are given for men under 25 years of age. This is due to the fact that no provision was made in the statistical forms for five year periods below this age. Such division was omitted because it was believed that a sufficient number had not been observed long enough to contribute any appreciable period of exposure. It seems likely, however, that the figures applying to the age period 25 to 29 apply also to those under age 25. Thus 8,252 men were observed at some time prior to age 25, the total group observed at some time between ages 25 and 29 was 10,123. In both groups the frequency of transient hypertension was approximately 4 per cent. Although the inference made is not based on proper statistical procedure, in that it disregards the length of the period of observation it probably approximates the fact. No observations were included beyond age 60 because adequate follow-up of these older men was possible in so few instances. This obtains also in the other tables.

The Later Occurrence of Sustained Hypertension, by Age, in Those With and Without Transient Hypertension (table 2)—In this and in subsequent tables the rates quoted are based on person-years observed. This method is employed to measure the total number of

TABLE 3—Disability Retirement Rate With Cardiovascular-Renal Diseases by Age for Those With and Without Transient Hypertension

Age	Person Years Observed *		Retirements with Cardiovascular-Renal Diseases		Rate per Thousand		Ratio
	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	
25-29	2,133	3,170	0	5	0.0	0.2	0.0
30-34	4,424	34,707	3	8	0.7	0.2	3.5
35-39	7,456	55,491	14	18	1.9	0.5	3.8
40-44	10,077	31,819	52	44	5.2	1.4	3.7
45-49	10,974	24,716	98	95	8.9	3.9	2.3
50-54	8,989	14,369	154	148	29.5	10.5	2.0
55-59	6,041	6,981	230	137	38.1	22.5	1.7

* This distribution of person years also constitutes the base for the rates in tables 4, 5 and 6.

years that all of the cases in each age group were exposed to the indicated risk. Some of the men will have been present throughout the given age period. Others will have come in during it, while still others may have dropped out before its end either because they left the service, retired or died. Each of these individuals must be credited with the proper amount of exposure during that age period for the purpose of computing rates on the usual annual basis.

It is at once apparent that, at all ages, sustained hypertension develops more frequently in those who have previously shown transient hypertension than in those who have not. The differences in each age group are significant. The rate per thousand persons per year, 1.6 per thousand person-years increases progressively in both groups with the ratio varying from 2.8 to 4.8.

Disability Retirement Rate with Cardiovascular-Renal Diseases, by Age, for Those With and Without Transient Hypertension (table 3)—The disability retirement rate is one index of the usefulness of an

TABLE 4—Disability Retirement Rate Excluding Cardiovascular-Renal Diseases, by Age for Those With and Without Transient Hypertension

Age	Disability Retirements Excluding Cardiovascular-Renal Diseases		Rate per Thousand		Ratio
	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	
25-29	4	61	1.9	2.0	1.0
30-34	18	114	4.1	3.3	1.2
35-39	42	1,043	9.7	3.8	2.5

55-59	48	1	7.9	10	0.8

officer to the Army. The figures under age 35 are not significant because of the small numbers involved. From 35 to 60 the retirement rate for cardiovascular-renal diseases is consistently greater among those with transient hypertension than in those without, and the difference in every age group above 35 is statistically significant. As the ages increase the ratio becomes smaller. This might have been anticipated since the

incidence of degenerative diseases increases in all persons in the older age groups, regardless of other factors. Reed and Love⁷ in their biometric studies of army officers noted that cardiovascular-renal diseases developing in later life were the most frequent causes of disability and death. Of officers who were active at age 46, 11.4 per cent subsequently had a disease of this type.

Disability Retirement Rate Excluding Cardiovascular-Renal Diseases, by Age, for Those With and Without Transient Hypertension (table 4)—The ratios in this table approximate unity, although there is a slight preponderance in favor of cases of transient hypertension. However, neither the individual differences nor the series of differences as a whole show clear statistical significance.

Many persons with a permanent elevation of blood pressure give a history of vasomotor and nervous

TABLE 5—Death Rate with Cardiovascular-Renal Diseases, by Age, for Those With and Without Transient Hypertension

Age	Deaths with Cardiovascular-Renal Diseases		Rate per 1 thousand		Ratio
	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	
	0	7	0.0	0.2	0.0
25-29	0	7	0.0	0.2	0.0
30-34	1	3	0.2	0.1	2.0
35-39	9	5	1.2	0.1	12.0
40-44	16	12	1.6	0.4	4.0
45-49	27	20	2.2	1.2	2.1

TABLE 6—Death Rate Excluding Cardiovascular-Renal Diseases, by Age for Those With and Without Transient Hypertension

Age	Deaths Excluding Cardiovascular-Renal Diseases		Rate per 1 thousand		Ratio
	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	
	5	176	2.3	5.7	0.4
25-29	5	176	2.3	5.7	0.4
30-34	10	121	4.3	3.8	1.1
35-39	44	104	6.0	2.9	2.1
40-44	80	60	3.9	2.8	1.4
45-49	46	74	4.2	3.1	1.4
50-54	43	62	4.8	3.6	1.3
55-59	33	37	3.5	5.3	1.0

instability earlier in life.⁸ In view of this fact it was thought worth while to determine the retirement rates with neuropsychiatric disorders in those with and without transient hypertension. Whereas a comparison of these rates shows a ratio favoring the group with transient hypertension consistently up to age 50, the differences are not great and considered individually or as a whole, are not statistically significant. Redetermination of the retirement rates excluding both cardiovascular-renal and neuropsychiatric diseases, shows them to be approximately the same in the two groups and, again, the differences are of no statistical significance.

Death Rate with Cardiovascular-Renal Diseases, by Age, for Those With and Without Transient Hypertension (table 5)—The figures under age 35 are not

significant because of the small numbers involved. From then on the death rate is consistently greater for those with transient hypertension, with rising figures in the older age groups. In fact the difference at every age over 35 is statistically significant.

TABLE 7—Survivals, Deaths and Retirements by Age 60 Among 10,000 at Age 25, According to the Death and Retirement Rates Among Officers With and Without Transient Hypertension Respectively

	Survivals	Deaths		Total	Retirements		Total
		With Cardiovascular-Renal Diseases	Other Causes		With Cardiovascular-Renal Diseases	Other Causes	
With transient hypertension	4,302	603	1,202	1,811	2,489	1,608	3,897
Without transient hypertension	5,608	379	1,118	1,467	1,357	1,073	2,975
Ratio	0.77	1.58	1.06	1.23	1.69	1.02	1.33

Death Rate Excluding Cardiovascular-Renal Diseases by Age, for Those With and Without Transient Hypertension (table 6)—As in the figures for disability retirement the death rate is slightly higher in the group with transient hypertension. The ratios are not as large however as in the death rates for cardiovascular-renal diseases. Although only one of the individual differences is statistically significant (that for the 35 to 39 age group), there is significance in the series of differences as a whole. In addition to cardiovascular-renal diseases neuropsychiatric disorders and suicide are excluded as a cause of death the rate remains slightly higher in the group with transient hypertension. The series of differences is still significant although much less so than before this exclusion. The reason for these differences is not evident.

The death rate with neuropsychiatric disorders after age 30 is uniformly and significantly higher in the group with transient hypertension. It should be stressed, however, that almost all of these deaths were due to suicide.

Summarized, Cumulative Actuarial Tables—In tables 7 and 8 the figures have been recast in actuarial form. In table 7 are given survivals, deaths and retirements by age 60 among 10,000 officers of age 25, according

TABLE 8—Survivals and Deaths by Age 60 Among 10,000 at Age 25, According to the Death Rates Among Officers With and Without Transient Hypertension Respectively

	Survivals	Deaths		Total
		With Cardiovascular-Renal Diseases	Other Causes	
With transient hypertension	7,777	877	1,400	2,223
Without transient hypertension	8,330	410	1,257	1,667
Ratio	0.9	2.01	1.11	1.76

to the death and retirement rates with and without transient hypertension. At the end of such an observation period there would be 4,292 survivors with a record of transient hypertension, contrasted with 5,608 without it—a ratio of 0.77. Among those who died of cardiovascular-renal diseases 603 would have had transient hypertension and 329 would not—a ratio of 1.85. Deaths from other causes among those with

⁷ Reed I. J. and Love A. G. Biometric Studies on Army Officers—Semiotical Norms in Disease. Human Biol. 5: 61 (Feb.) 1933.
⁸ O'Hare, J. P., Walker W. G. and Vickers M. C. Heredity and Hypertension. J. A. M. A. 83: 27 (July 5) 1924.

transient hypertension would have been 1,202, as against 1,138 among those without—a ratio of 1.06

With respect to retirements for disability with cardiovascular-renal diseases, there would have been 2,289 in the group with transient hypertension and 1,352 without—a ratio of 1.69. Retirement for other causes would have occurred 1,608 times in the group with transient hypertension and 1,573 in the group without—a ratio of 1.02

In table 8 appear the survivals and deaths by age 60 among 10,000 officers at age 25, with and without transient hypertension, according to the death rates only. At age 60 there would be 7,777 survivals among those with transient hypertension and 8,333 without—a ratio of 0.93. Deaths from cardiovascular-renal diseases for those with transient hypertension would number 823, as against 410 for those without—a ratio of 2.01. Deaths from other causes would number 1,400 in those with transient hypertension and 1,257 in those without—a ratio of 1.11. These tables bring into focus, in condensed form, the higher rates of disability, retirement and death in the group with transient hypertension.

COMMENT

The upper limits of the normal blood pressure have not been firmly established. The critical levels of 150/90 used in this study are those prescribed in Mobilization Regulations 1-9, issued by the War Department on Oct 15, 1942. The standards of physical examination for commission in the Regular Army, according to Army Regulations 40-105, define hypertension as a persistent systolic blood pressure of 150 or more or a persistent diastolic of 95 or more if the candidate is over 25 years of age, and a persistent systolic of 140 or more or a persistent diastolic of 90 or more if the candidate is less than 25 years of age. It has seemed proper to accept 150 systolic and 90 diastolic as the upper limits in this study because of the large numbers now involved in Selective Service examinations. The relative importance of various higher levels, both systolic and diastolic, will be considered in a forthcoming publication.

No mention has been made of the condition of the retinal vessels. Records concerning them were available in so few cases that no conclusions are justified. The cold pressor test⁹ was not employed in any of these examinations, but hyperreaction to cold and to emotion appear to carry similar implications.

Two recent papers have appeared dealing with the problem of transient hypertension in the Navy. Master¹⁰ called back for reexamination 50 patients, all 40 years of age and over, who during their stay in the hospital one to seven years previously had shown blood pressure readings at the upper limits of normal. These varied from 140 to 156 systolic and 80 to 94 diastolic. There was only a single reading for each patient. On reexamination, 76 per cent were found with hypertension and at least 25 per cent had a diastolic pressure over 100. It was concluded that even one high reading may be an indication of future hypertension and that some men with such levels may already have cardiovascular disease. The suggestion was made that in borderline cases a complete physical examination should be performed and the final decision should be based on the composite picture presented.

A somewhat more liberal point of view has been expressed by Rogers and Palmer.¹¹ During one month at the Office of Naval Officer Procurement, Boston, they found that 222 of 1,574 applicants (14 per cent) had mild variable hypertension at the initial examination. Their recommendations, however, are based on a favorable follow-up experience, in civilian life, with 25 cases of nervous hypertension and 448 cases of early and late essential hypertension. They suggest criteria for the acceptance of applicants who show a labile blood pressure and conclude that transient nervous hypertension, taken as the first sign of essential hypertension, need not be disqualifying for military service.

The results of the present study must be applied according to the need for men in the armed forces. It is clear that persons who show a transient elevation of blood pressure above 150 systolic or above 90 diastolic are more likely to show sustained hypertension at a later date than those whose readings remain below these levels. In addition the transient hypertension group shows higher rates for disability, retirement and death from some form of cardiovascular-renal disease than does the group with a consistently normal blood pressure. It is also apparent that in those with transient hypertension there are slightly higher death rates from diseases other than those affecting the cardiovascular system and kidneys. This is explained in part, though not entirely, by the higher mortality, in this group, from nervous and mental diseases, and particularly from suicide. The same general trend is evident in the retirement rates, although here the differences are not clearly significant.

SUMMARY AND CONCLUSIONS

1. An analysis has been made of the medical records of 22,741 officers of the United States Army in order to appraise the significance of transient hypertension. Blood pressure readings over 150 mm of mercury systolic or over 90 diastolic were considered abnormally high.

2. The length of the observation period was from one year to more than twenty-five years, 84 per cent were under observation from five to nineteen years and 38 per cent from fifteen to nineteen years. In 1,437 instances the duration of the observation period was twenty years or over. These figures are quoted from the first paper in the series.⁶

3. The frequency with which transient hypertension was first noted increased with age. The curve of increase was smooth, beginning with 5.9 per cent in the age group 25 to 29 and reaching a plateau of 18.6 per cent at 50 to 54.

4. At all ages, sustained hypertension developed more frequently in those with previous transient hypertension than in those who never showed an elevation of blood pressure. In both groups the rate increased with advancing years.

5. The rate for disability retirement with cardiovascular-renal diseases, which is one index of the usefulness of an officer to the Army, was consistently higher among those with transient hypertension than in those without, at all ages from 35 to 60.

6. The death rate with cardiovascular-renal diseases was also higher in those with transient hypertension, the figures rose in the older age groups.

7. Both disability retirement and death rates from diseases other than those of cardiovascular-renal origin

9. Hines E. A. Jr. and Brown G. E. A Standard Test for Measuring the Variability of Blood Pressure. Its Significance as an Index of the Prehypertensive State. *Ann. Int. Med.* 7: 209 (Aug.) 1933.

10. Master A. M. Cardiovascular Problems in the War. Hypertension and the Navy. *Bull. New York Acad. Med.* 19: 704 (Oct.) 1943.

were slightly higher in the group with transient hypertension. In the case of the retirement rates the differences were not significant. The higher death rates in the group with transient hypertension were explained in part, though not entirely, by the relatively greater number of suicides.

8 The decision as to the usefulness to the Army of a man with transient hypertension will depend on the need for manpower. If this is urgent he may be accepted, provided heart, arteries and kidneys are normal. In doubtful cases the examination should include a teleroentgenogram of the heart and an electrocardiogram, as well as examination of the retinal vessels and urine. A certain number so accepted will develop permanent hypertension and the number will increase as age advances, in this series the rate per thousand ranged from 5.6 between the ages of 35 and 39 to 48.0 between 55 and 59. During times of peace, or whenever the need for men in the service is not acute, the transient hypertensive is not to be regarded as a first rate risk, he may later prove a burden to the Veterans Administration.

9 It seems probable that the facts pertaining to transient hypertension which have been derived from an analysis of the records of army officers apply also to the general male population of comparable physical fitness and similar age groups.

ABSTRACT OF DISCUSSION

DR E. A. HINES JR., Rochester, Minn. It is often stated in articles in medical textbooks and periodicals that transient elevations of blood pressure are due to nervous tension and therefore are of no significance. It is usually further advised that subsequent blood pressure readings should be taken when the subject is more relaxed and that the lowest reading should be recorded as the proper blood pressure reading. The proponents of the idea that such elevations of blood pressure are of no significance have offered no proof that this is so. As Dr. Levy has indicated, there are those who believe that transient elevations of the blood pressure particularly in the diastolic blood pressure may be indicative of a prehypertensive state, if not actually representative of the earliest stages of hypertensive disease. The data which Dr. Levy and his associates have presented are another link in the chain of evidence supporting this contention. Dr. Levy has concluded that transient elevations of blood pressure are probably of some significance in the subsequent development of hypertension. He has not been able to state or to show just what should be done with the individual with an elevation of blood pressure which sometimes goes into the upper range of normal. For instance, what should be done with a person 20 years of age who has a blood pressure of 150 systolic and 95 diastolic or what should be done with a person of 30 who has a blood pressure of 145 systolic and 90 diastolic? The answer to this question—and it is a most pertinent one—probably cannot be obtained as far as concerns the armed services without a long term follow-up study of a group of young men and women which is sufficiently varied and adequately controlled and who have had special blood pressure studies carried out and have been followed in the armed services through varying types of duties and for from ten to twenty years afterward.

DR ROY W. SCOTT, Cleveland. Both the large number (22,741) and the length of time over which the observations of Dr. Levy and his colleagues extended make this study of great statistical value. Clinicians may now speak with increasing assurance about certain concepts based on personal experience gained in following patients with vascular disease and hypertension. Among these is the more frequent appearance of sustained hypertension at all ages in persons with previous transient hypertension. Since transient hypertension is a frequent forerunner of sustained hypertension which in turn is so often associated with arterial and arteriolar disease one would expect, as these workers have found that both the rate of disability

retirement and the death rate from cardiovascular renal disease are higher in persons with transient hypertension. These data are so consistent with clinical experience among the civilian population that the facts derived from their analysis of the records of army officers probably apply to our male population of comparable physical fitness and similar age group.

DR N. S. DAVIS III, Chicago. It seems that the syndromes characterized by arterial hypertension develop whenever the auxiliary humeral renal-hypertensin pressor mechanism becomes permanently established. This occurs when "emotional" hypertension or that caused by fatigue overexertion or exposure to cold or high altitude is of sufficient duration to exhaust the adrenals and prevent the secretion of adequate amounts of epinephrine when there is hypoadrenalism with the formation of toxic steroids which inhibit renal amino acid oxidation when adrenal corticosterones are increased sufficiently to inhibit renal amino acid oxidation when there is renal ischemia due to vasoconstriction of anomalous arteries or when the formation or action of renal amino acid oxidases is inhibited because of exposure to toxic chemicals to toxic metabolic and bacterial products of disease or because of deficient intake, absorption and utilization of minerals, amino acids and vitamins required for their synthesis. When renal oxidation is inhibited deamination of amino acids is by decarboxylation with the formation of pressor amines which cause local foci of renal ischemia and the formation of renin. The renin reacts with the alpha globulin hypertensinogen to form hypertensin which causes more renal vasoconstriction and so increases renin formation. Thus the renin-hypertensin pressor mechanism tends to establish itself and initiate the insidiously progressive syndrome with which high arterial tension is associated.

DR ROBERT L. LEVY, New York. Although as a group those showing a transient elevation of blood pressure are more likely later to develop sustained hypertension and various manifestations of cardiovascular-renal disease this sequence of events is by no means invariably observed. Our next problem is to define, if possible, adequate criteria for the recognition of those persons in whom transient hypertension is an early sign of future trouble.

Clinical Notes, Suggestions and New Instruments

SULFADIAZINE SENSITIVITY

THE CAUSE OF SEVERE TOXIC SYMPTOMS IN A CHILD

PHILLIS KOTEEN, M.D., NEW YORK

This case is reported because of severe and unusual manifestations of sulfadiazine idiosyncrasy and diagnostic and therapeutic problems involved.

P. R.,¹ a white boy aged 5½ years, was admitted to the private pediatric service of the New York Hospital on Feb. 24, 1944 with the chief complaints of fever and cough of four days' duration.

Two years prior to admission the patient suffered from otitis media and mastoiditis for which he was treated at another hospital with sulfadiazine and sulfathiazole. His mother believed that hematuria had occurred with sulfadiazine therapy and fever and a rash with sulfathiazole. Following this illness the patient remained well except for respiratory infections until the onset of the present illness.

The present illness began February 6, eighteen days before admission, with fever and sore throat, which improved without specific therapy. Ten days prior to admission a sibling had a streptococcal sore throat and rash. On February 18 the patient vomited complained of slight abdominal pain and had three loose bowel movements. The following day he started to cough. Two days later sulfadiazine therapy was begun because of a temperature of 39 C (102.2 F), signs of a severe respiratory infection and tonsillitis. He received 0.75 Gm every four hours for a total dosage of 9 Gm. Absence of

From the Department of Pediatrics of the New York Hospital and Cornell University School of Medicine.
¹ Dr. Benjamin Spock gave me permission to report this case.

response led to discontinuance of the drug, and on the following day he was admitted to the hospital.

On admission examination revealed that the patient was moderately well developed, slender, flushed and listless, but he did not appear severely ill. His temperature was 39 C rectally. The skin was dry and showed a fine brawny desquamation at the left wrist where a few pink maculopapular lesions. The nasal turbinates were inflamed, the tongue was coated and dry. The tonsils were hypertrophied and injected. Examination of the chest revealed increased tactile fremitus, exaggerated breath sounds and rhonchi throughout the right side. The abdomen was diffusely tender, the spleen was firm and was palpated 2.5 cm below the costal margin, the liver was felt 1 cm below the costal margin in the midclavicular line. The remainder of the examination was negative.

On admission the hemoglobin was 11 Gm, the red blood cells were 4.4 million and the white blood cells were 12,000, with a differential of 17 per cent lymphocytes and 83 per cent polymorphonuclear leukocytes. On smear no abnormal blood cells were noted, and the platelets appeared adequate. The urine was clear and yellow with a specific gravity of 1.025 and without albumin, sugar, red cells, white cells or casts. Subsequent urine examinations led cell counts and hemoglobin

Temperature chart, therapy and essential laboratory data

determinations remained normal. The changes in leukocyte count, differential and platelets are recorded in the accompanying chart. Daily blood cultures taken for the first five days showed no growth. Initial throat cultures grew a few beta hemolytic streptococci and *Hemophilus influenzae*. Repeated blood agglutinations for the typhoid-paratyphoid group, Brucella, rickettsial organisms and heterophile antigen were negative. X-ray examination of the chest gave normal results.

On the second hospital day the patient's temperature reached 40.8 C (105.4 F), his tonsils appeared more injected and the cervical glands seemed larger. On the assumption that this infection was caused by the beta hemolytic streptococcus, 100 cc of anti scarlet fever convalescent serum was administered. The following day this high fever was maintained, and the patient appeared very toxic and developed a diffuse morbilliform rash. An additional 100 cc of convalescent serum was given without effect. Because of the questionable history of sulfonamide sensitivity these drugs were not used.

Despite the report of no growth in the first blood culture, septicemia appeared the most likely diagnosis. For this reason penicillin therapy was started on the third hospital day. He received a total of 500,000 units in the subsequent four days. During this interval the throat infection and cervical lymphadenitis subsided entirely; however, the patient's condition became critical, he was semicomatose and generalized edema developed. The temperature ranged from 39 to 41 C (102.2 to 105.8 F), the rash became more extensive and numerous petechiae appeared. It was apparent that penicillin was not influencing the general course of the disease and many unusual febrile illnesses were considered as a possible cause of this boy's serious condition. On the eighth hospital day it was

noted that the patient's blood in a tube did not clot for thirty minutes. The prothrombin level² was found to be 54 per cent of normal, and the platelet count³ was 8,000 on this day. The diagnosis of sulfadiazine sensitivity with thrombocytopenia and severe generalized toxic symptoms seemed justified. This opinion was substantiated by a sulfadiazine blood level of 2.3 mg per hundred cubic centimeters four days after cessation of the therapy and the presence of detectable amounts of the drug in the blood after twelve days.

The patient received several direct transfusions and showed gradual clinical improvement and rise in platelet count. However, on the eighteenth day the white count fell precipitously to 2,200 with complete disappearance of the granulocytes. He was given 2 cc of liver extract and 10 cc of pentnucleotide daily for eight days. His improvement was steady thereafter and he was discharged on the thirty-seventh hospital day, at which time his blood picture had returned to normal. He was clinically well with the exception of remaining hepatosplenomegaly.

After discharge details of the patient's previous hospitalization became available. He had been hospitalized two years previously because of otitis media and mastoiditis. He was given sulfadiazine therapy, and ten days after initiation of this treatment he developed a rise in temperature, generalized maculopapular rash, lymphadenopathy and hepatosplenomegaly. Sulfathiazole was given a few days later because of tonsillitis. The patient responded with anuria, a hemorrhagic rash and continued hepatosplenomegaly. A reduction in the polymorphonuclear leukocytes occurred eight days after discontinuance of the sulfathiazole.

If this record had been available at the time of the patient's hospitalization there would have been no diagnostic problems. However, he would still be of interest because of the variety and severity of toxic manifestations presented by 1 patient. Hepatosplenomegaly has rarely been reported as a complication of sulfonamide therapy. Williams⁴ reports 1,000 cases of infection treated with sulfapyridine. Twelve of these patients developed rashes, and 9 had concurrent hepatosplenomegaly. One case fully reported was similar to ours, with a severe toxic reaction, purpuric rash, edema, enlarged liver and spleen and basal rales. No mention was made of platelets, and there was leukocytosis with eosinophilia in contradistinction to our case.

There have been only a few instances of thrombocytopenic purpura noted resultant from all forms of sulfonamide therapy. When this complication does occur it is apt to be extremely serious.⁵ Five out of 9 cases reported terminated fatally. An additional case of thrombocytopenia following three weeks of sulfadiazine therapy occurred in a boy aged 5 years in our wards.⁶ He developed a picture resembling the Waterhouse-Friedrichsen syndrome with diffuse hemorrhages into the skin, shock and a low platelet count. Autopsy revealed massive hemorrhages into the adrenals, which seemed satisfactorily accounted for by the depressed platelets and not by septicemia. These reactions appear to be definitely due to sensitivity to sulfonamides and not to direct toxic reaction of the drug on the platelets. Kracke and Townsend⁷ followed 61 patients receiving sulfathiazole and found an increase in the platelet count during the course of therapy.

The other reactions exhibited by our patient such as hyperpyrexia, rash and agranulocytosis, are of more frequent occurrence and have hitherto been reported adequately.⁸

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application

AUSTIN SMITH, M D, Secretary

ALLERGENIC EXTRACTS (See New and Nonofficial Remedies, 1944, p 35)

ENDO PRODUCTS, INC., RICHMOND HILL, N Y

Allergenic Extracts The following extract is marketed in treatment set packages of four 10 cc vials containing respectively, slightly more than 1 cc of a 2.5 per cent, 0.25 per cent, 0.025 per cent and 0.0025 per cent dilution of the original extract in glycerosaline solution (50 per cent glycerin) and four 10 cc vials containing 9 cc of diluting fluid (0.4 per cent phenol in isotonic solution of sodium chloride). The extract is also supplied in special treatment packages of one 10 cc vial containing 4 cc of a 2.5 per cent dilution of the original extract in glycerosaline solution (50 per cent glycerin) and one 10 cc vial containing 6 cc of diluting fluid (0.4 per cent phenol in isotonic solution of sodium chloride)

House Dust (Purified Concentrate)

Allergenic extract house dust (purified concentrate) Endo is prepared from dust obtained from mattresses and household furniture

A mixture of 1 part by weight of house dust and 2 parts by volume of distilled water is covered with toluene and extracted while stirring at 0 to 5 C for seventy-two hours. The aqueous extract is separated from the dust by centrifugation

Three volumes of the water extract are cooled to 0 to 5 C and treated with 2 volumes of previously cooled acetone. The precipitated material separated by centrifugation is discarded. Acetone is added to the clear centrifugate until a concentration of 75 per cent acetone is reached. The precipitated material is centrifuged and the liquid is discarded. Adhering acetone is blown off with cold dry air. The precipitate is taken up in one tenth the original volume of distilled water. Three volumes of this aqueous solution are treated with 2 volumes of acetone mixed thoroughly and centrifuged. The liquid is reserved. The residue is washed with a small amount of a 40 to 60 per cent V/V acetone-water solution until the original volume of supernatant and wash liquids is equal to one tenth the original volume. Sufficient acetone is added to yield a 75 per cent concentration. The syrupy precipitate is separated by centrifugation and the adhering acetone is removed by cold dry air. The syrup is taken up with one tenth the original volume of distilled water and dialyzed against running distilled water until about 50 per cent of the total dissolved solids has been removed. To the 5 per cent solution w/v (adjusted by low temperature vacuum distillation if necessary) obtained by dialysis sodium chloride is added (1.8 Gm per hundred cubic centimeters) and the solution is passed through a Seitz filter. The sterile solution is added to an equal volume of previously sterilized glycerin. This solution of 2.5 per cent allergenic extract constitutes the stock solution from which appropriate dilutions are prepared. All diluted solutions are passed through a Seitz filter before filling into sterile vials by aseptic technique

Allergenic Extracts Diagnostic The following extract is marketed in packages of a single vial, with accompanying applicator containing 1 cc of a 1:200 solution (0.5 per cent) of the original extract in 50 per cent glycerin

House Dust (Purified) Concentrate

This extract for use by the scratch method and cutaneous testing is prepared in much the same manner as the allergenic extract Endo for treatment just described. The procedure is the same up to the point of dialysis whereupon the extract for diagnosis undergoes the following treatment. To the solution obtained immediately before dialysis ammonium sulfate is added (60 Gm per hundred cubic centimeters). The coagulated material is centrifuged. The separated solid is dissolved in one half the original volume of distilled water and the ammonium sulfate precipitation is repeated. The solid separated by centrifugation is suspended in a small volume of water and dialyzed until the solution in the sac does not respond to tests for the sulfate ion. The dialyzed solution is centrifuged to remove a small amount of suspended solids and the solution is adjusted (by vacuum distillation at low temperature if necessary) to contain 1 per cent of dissolved solids. Sufficient sodium chloride is added to yield a 1.8 per cent solution with respect to sodium chloride. The solution is diluted with an equal volume of glycerin and filtered through a Seitz filter. This 0.5 per cent solution constitutes the allergenic extract purified house dust concentrate for diagnosis by scratch testing

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article

HOWARD A CARTER, Secretary

ARTIFICIAL RESPIRATION—MANUAL AND MECHANICAL

In all cases of asphyxia it is of paramount importance that artificial respiration be administered immediately. Loss of a minute may mean the difference between life and death. There is little hope of reviving a victim who has ceased to breathe for more than five to seven minutes and even less chance if he has been in a state of apnea for more than ten minutes. Effective artificial respiration may be applied by the acceptable manual methods—Schafer prone pressure and Howard-Silvester methods—or by mechanical means—respirator or resuscitator. The inhalator is a valuable adjunct to manual methods of artificial respiration. One disadvantage to mechanical apparatus, either resuscitator or inhalator is that it is not always on the scene of an accident and precious first minutes or seconds may be lost waiting for its arrival

All rescue crews, and also the public should be taught a correct method of administering manual artificial respiration. The one most generally used is the Schafer prone pressure method, which may be administered effectively by one person. The American Red Cross, the Boy Scouts and the Y M C A give instruction in this method. Physiologic experiments prove that an exchange of air in the lungs is achieved when the method is applied correctly. The Council highly recommends that every man, woman and child take advantage of the opportunity made available through defense activities to learn how to apply manual artificial respiration

The Howard-Silvester method is somewhat more cumbersome to administer and requires the services of a team of trained persons. The Coast Guard uses this method

In 1932 Dr F C Eve of Hull, England, described a new method of artificial respiration which is unlike all previous methods mentioned. It is a rocking method and the force of gravity causes the abdominal organs to shift, thus moving the diaphragm in and out like a bellows. It has been adopted on the British warships. In Eve's method the drowning victim is laid face downward on a stretcher and is well wrapped with blankets. His wrists and ankles are lashed to the handles. Then he is hoisted on a trestle or sling and rocking is begun. This method, according to Dr Eve, is best because in cases of drowning the inspiratory recoil may be lost as the result of loss of tone in the diaphragm, and it is independent of tone. This method is safe and can be done by any one, but the disadvantage is that the equipment, although simple, may not be on hand in emergency cases when it is needed

Included in the Council's list of accepted devices are inhalators and resuscitators, the two types of apparatus for administering mechanical artificial respiration. These devices are often confused as to function, the following briefly describes them

Inhalators provide an atmosphere of oxygen and carbon dioxide gas mixture slightly higher than atmospheric pressure around the mouth and nose of the victim and are used in conjunction with an approved method of manual artificial respiration. Inhalators consist essentially of a face piece, rubberized fabric breathing bag, pressure reducing valve, tanks of carbon dioxide-oxygen mixture and carrying case

Resuscitators create positive and negative pressure by means of a mechanical appliance operated by the energy of the stored gas merely positive pressure only. A face piece, reduction valve, tanks of carbon dioxide-oxygen mixture or merely tanks of oxygen, a carrying case and a reciprocating mechanism are the principal parts of the resuscitator

The efficacy of the two types of appliances has been shown to be essentially the same by the evidence coming to the Council. Records show that when an inhalator and a resuscitator are on the scene of an accident at the same moment and if either one is employed efficiently, the final result will not differ

The Council on Physical Medicine is now carrying on a five year survey and is supporting research on artificial respiration. It is hoped that this work will produce additional data

ENVIRONMENTAL CANCER

Environmental cancer is cancer due to prolonged contact with some cancerogenic agent in the environment. The relationship of a previous exposure to such an agent and the cancer often appearing many years later is frequently overlooked or not understood. Environmental cancers can be divided into four main groups according to the type of exposure.

First are the cancers caused by agents in the normal environment. Representative of this group is cancer due to the continued ingestion of arsenic in drinking water and foodstuffs in certain regions, the solar cancers of the skin in dry and sunny regions, as in our Midwestern and Southwestern states, the bladder cancers in people in places like Egypt with endemic schistosomiasis, and possibly also lung cancers due to inhalation of road dust containing cancerogenic tar. The second group of environmental cancer results from certain habits (habitual cancer), as for example cancer of the lip and mouth in smokers, cancer of the oral lining in betel and tobacco chewers, and cancer of the abdominal skin in kangri users. The third group comprises cancer resulting from use of certain medicinal agents (medicinal cancers), e. g. cancer of the skin after arsenical medication and after exposure to roentgen rays and radioactive substances. The fourth, which is the largest and most important group, is represented by occupational cancer elicited by exposure to chemical and physical agents in the course of regular occupations.¹

The agents known or suspected to cause occupational cancer are arsenic, chromates, nickel carbonyl, radium, mesothorium, asbestos, crude and processed mineral oils,

pitch, tar, soot, paraffin oil, anthracene oil, creosote, aromatic amino compounds (aniline, naphthylamine, benzidine), benzene, ultraviolet rays, roentgen rays, radioactive materials and substances from certain parasitic worms. Approximately 8,000 to 9,000 cases of occupational cancer appear to have been placed on record, the majority during the last two to three decades, during which the sources of occupational cancer were mostly discovered. These figures, however, do not reflect the actual incidence of industrial cancer, as the cause of many cases of this type is not properly recognized or their occurrence is not recorded.

Environmental cancer may involve many organs and tissues, notably the skin, lip, tongue, cheek, oral cavity, nasal sinuses, larynx, bronchi, lung, liver, kidney, ureter, bladder, connective tissue, bone and hemopoietic tissues. The site of the cancer depends on the type of the cancerogenic agent and the kind of exposure. The sex ratio is determined mainly by the exposure to the various cancerogenic agents. It is for this reason that the male sex is predominantly affected by occupational cancer, but osteogenic sarcoma occurs in women working in luminous dial factories. Undoubtedly the rapid increase in the employment of women in hazardous industries will be followed by an increase of occupational cancer in women.

The public health importance of industrial cancer undoubtedly will increase not only with respect to the number of workers, male and female, exposed to industrial cancerogenic agents but also with respect to the variety of plants and operations in question. Public health authorities will wish to institute effective technical and sanitary supervision of such establishments as well as medical control of the workers, present as well as past. Practitioners and cancer clinics, in addition to industrial physicians, will aid greatly in meeting this situation by close study of the occupational history of all patients coming to them with precancerous and cancerous lesions. It is mainly in this way that the industrial origin of cancer can be established and new sources of occupational forms discovered. The benefits from such efforts will be not only the early detection and improved prognosis of cases of occupational cancer but also the prevention of industrial cancer by the elimination of exposures to cancerogenic agents. Industrial cancer is largely preventable by proper technical measures.

Organized investigation of environmental and especially occupational cancers is a promising approach to the study of fundamental problems of human cancer because these cancers are the counterpart of experimental cancer in animals. Environmental cancers permit a scientific analysis of cancerogenic agents and of local and general reactions induced by them in human beings.

TRANSITORY PULMONARY INFILTRATIONS ASSOCIATED WITH EOSINOPHILIA— LOEFFLER'S SYNDROME

Loeffler reported in 1932 and again in 1936¹ a syndrome characterized by transitory pulmonary infiltrations, blood eosinophilia and a mild clinical course which was in striking contrast to the extensive pulmonary lesions as seen in the roentgenograms. Some of the cases were discovered in supposedly normal persons in the course of mass radiography, while others were in ambulatory cases suspected of pulmonary tuberculosis. Symptoms when present were those of fatigue, irritating cough, associated sometimes with pain in the chest and with scanty sputum, normal or moderately elevated temperature, mild leukocytosis, and increased sedimentation rate. Exaggerated vesicular breathing and sibilant rales over the area of infiltration were the only auscultatory signs. The eosinophilia ranged from 6 per cent to 66 per cent and accompanied rather than followed the appearance of the infiltration of the lung, so that it could not be considered a post-infectious phenomenon. However, strict parallelism between the extent of the infiltration and the grade of eosinophilia was not demonstrable.

The essential and distinguishing feature of the syndrome as emphasized by Loeffler is the fleeting, migratory character of the infiltrations. The shadows appear and disappear in from three to eight days. They may be extensive and irregular in shape or small and round, resembling remarkably the shadows of primary tuberculous infiltration, they may be fleecy or dense, unilateral or bilateral, they may involve the entire lung or be limited to one lobe. In a small number of cases Loeffler observed involvement of the pleura with occasionally small circumscribed pleuritic effusion. Breton² likewise stresses the fleeting, migratory and in some cases recurring character of the x-ray shadows in the Loeffler syndrome and points out that attacks of asthma, which, according to various authors, accompany the syndrome in from 5 to 8 per cent, need not be considered as an essential feature of the syndrome. The syndrome is observed more frequently in asthma because the latter is the most frequent allergy.

Pathologic observations on this condition are limited to postmortem studies of Meyenburg³ on four accidental deaths. He found that the infiltrations were of pneumonic type with exudation into the alveoli and with eosinophilic infiltration of both the alveoli and the interstitial tissue. There was also an inflammatory involvement of the pleura and of the interlobar fissures. Meyenburg failed to demonstrate tubercle bacilli or *Ascaris* larvae in the pulmonary tissue.

The etiology of the syndrome is obscure. Loeffler first suspected that these cases represented a mild atypical form of pulmonary tuberculosis. Maier⁴ reviewed the 100 cases seen at Loeffler's clinic in Zurich and found only 2 patients with active tuberculosis at the time of sickness, the tuberculous process was present in both for some time. The first important contribution to the etiology of the syndrome is probably that of Engel, who had observed seasonal occurrences of cough in Shanghai which coincided with the flowering of the privet plant. Fifty-two of the 100 cases in Maier's series displayed such allergic phenomena as eczema, hay fever, migraine, vasomotor rhinitis and urticaria either before or at the time of the illness. The blood eosinophilia of course suggested the allergic character of the disease. Swiss observers emphasized the rather frequent association of the syndrome with *Ascaris* infestation. Thus Zweifel⁵ found sensitivity to *Ascaris* extract in 70 per cent of the cases with the Loeffler syndrome, whereas normal persons, persons with ascariasis and allergic persons reacted to it in only 40 per cent. Zweifel concludes that, while *Ascaris* appears to be the most frequent cause of these pulmonary infiltrations, it is not the exclusive allergen. Lavier⁶ reported a case of hepatitis associated with Loeffler's syndrome caused by the liver fluke (*Fasciola hepatica*). Hoff and Hicks⁷ reported a case in which asthmatic attacks and pulmonary infiltrations which persisted for three months disappeared dramatically on the discovery and treatment of *Endameba histolytica*. The syndrome appears to represent a genuine allergic phenomenon, the pulmonary tissues constituting the shock organ. Gravesen⁸ stresses that it is the interstitial tissue of the lung that is hypersensitive rather than the bronchi, as is the case in asthma. The cases in which ascariids appear to be the cause raise the question whether the pulmonary infiltrations are the result of invasion of the lungs by the larvae of the helminth or whether these infiltrations represent a purely allergic inflammatory reaction in response to the *Ascaris* toxin. Most observers, including Maier, failed to find the larvae of the ascariids in the sputum. The only support for the thesis of this being an *Ascaris* larva pneumonia is the experiment of Koino, in which he swallowed 2,000 larval eggs of ascariids with resultant pneumonic consolidation and sputum containing larvae. This experiment of course is not necessarily comparable to the natural evolution of the disease.

For the present it may be assumed that Loeffler's syndrome is an allergic reaction that can be provoked by a variety of allergens. The relationship of tropical eosinophilia to Loeffler's syndrome is not clear, according to Apley and Grant⁹ the two conditions are similar and are not clearly distinguishable.

Current Comment

THE 1945 ANNUAL SESSION IN PHILADELPHIA

As indicated under the Organization Section in this issue of THE JOURNAL, the Board of Trustees, through authority vested in it by the constitution of the Association, has transferred the annual session for 1945 from New York City to Philadelphia. The dates are June 18 to 22 inclusive. Because of the tremendous demands on the hotels for rooms, physicians are asked to cooperate by refraining from making a reservation in more than one hotel, also by limiting their reservations to the minimum amount of space that they need to occupy. Physicians are asked to share accommodations by utilizing a double room with another physician whenever that is convenient. The medical profession of Pennsylvania and of Philadelphia and all of the groups in Philadelphia concerned in the holding of this session promise to do their utmost to aid the success of the meeting.

MATURITY AND THE COMPLETION OF HIGHER EDUCATION

The average age of students who complete their formal programs of higher education, including that in medicine, has shown a consistent rise during the past century. The only exception has been the recent reversal due to the war. Pressey,¹ who has recently reviewed the history of this trend in the United States, points out that many efforts have been made to counter this development over the same period. A great variety of evidence, he says, medical, psychologic, educational and sociologic, indicates that maturity of the human organism is reached at about 20 and that thereafter only a relatively few years remain at prime. Before the war the average age of obtaining the M.D. degree was 28, consequently many of the best years are spent in learning rather than in "doing." Pressey's plea is that completion of programs of higher education is desirable—preferably about two years earlier than was usual before the war. In the field of medical education this problem is peculiarly complex, the subject deserves discussion and study, but decision as to the desirability of a shortened course with graduation at an earlier age should not be unduly influenced by the abnormal conditions of medical training which exist during the war.

UNUSUAL BRAVERY OF THE MEDICAL CORPS

The heroic and self-sacrificing acts of many men of the medical corps have been repeatedly noted under Medicine and the War in THE JOURNAL. Feats of combat pilots, gunners, submarine crews, pioneer troops and tank crews are frequently vividly described in the newspapers. Physicians with the armed services are daily performing great and small acts of heroism in the care of the sick and injured. Often their work is unnoticed beyond the small group in which they regularly do their professional duties. A War Department release of November 19 announces the award of the Silver Star to five men, of whom three were members of the Medical Corps of the Army of the United States. Among twenty-two men awarded the Bronze Star Medal, seven were medical officers and eight enlisted men of the Medical Department. Nearly all of the citations were given for the high devotion to duty displayed by medical officers in going to the aid of wounded soldiers in the face of intense enemy infantry and artillery fire with utter disregard for their own personal safety. This record all doctors may share with pride.

THE TRANSFORMATION OF NORMAL CELLS INTO CANCER CELLS

In his review of recent work on cellular transformations, Haddow¹ pays special attention to cytoplasmic mechanisms in cancer. In cell division different characters in cells with the same nuclear genes may result from a differential segregation of cytoplasmic constituents and "determiners." The change of normal cells into cancer cells is a most remarkable transformation. This change occurs spontaneously, and experimentally it can be produced by, cancerogenic chemicals, x-rays and other radiations. Generally speaking, the change involves more or less loss of differentiation with gain in the rate of growth. Not infrequently specific differentiation cannot be recognized. The change is permanent and irreversible—the cancer cell continues to multiply as such in the original host, in transplants to new hosts and in cultures outside the body. But this multiplication is not dependent on the presence of the agent which started it. As Haddow puts it "it is patent that the carcinogen does not provide the real stimulus to growth, since growth proceeds without it. Hence the mechanism which permits unlimited growth must clearly reside in the cell itself." What the carcinogen appears to do is to change permanently the normal mode of growth of the cells, and this change is inheritable. In the light of the current developments in cytogenetics it is Haddow's conclusion that the mechanisms of the unlimited growth of the cancer cell "may reside partly at least in the cytoplasm."

MEDICINE AND THE WAR

ARMY

CONFERENCE OF FLIGHT AIR SURGEONS

Top flight air surgeons from all fighting theaters recently conferred at the AAF Personnel Distribution Command Atlantic City, and assumed duties of flight surgeons consultant in army general and service forces regional hospitals all over the country. Specially selected by the chief of the Professional Services Division they will confer with hospital authorities on aviation medical matters and visit air forces patients and discuss individual problems relative to transfer to AAF medical facilities or to duty on a flying status in the Air Forces through the PDC.

he and an ambulance driver proceeded to the scene. The wrecked aircraft was burning rapidly, creating an imminent danger of the high octane gasoline or the bomb load exploding. He climbed along the wing until he ascertained that the pilot was not in the forward cockpit, while the ambulance driver searched the rear section for the gunner. With 0.50 caliber ammunition exploding from the plane they also searched the area until first one crew member and then the other were located from 200 yards away. During this time the bombs exploded while these men were only 40 yards from the wreckage. Escaping injury, they administered to the injured fliers

Top flight air surgeons at the conference. Standing left to right: Major A. A. Sprong, Sterling, Kan., from Hawaii and the South Pacific; Major D. E. James, Belvidere, Ill.; China Burma India theater; Major L. M. Kistler, Los Angeles, India; Capt. J. H. Arrington Jr., Columbia, Mo.; eye, ear, nose and throat specialist; Major G. R. Elliott, Orange, Va.; European theater; Capt. E. W. Furgurson, Plymouth, N. C.; India Burma; Major J. M. Sniolen, Erie, Pa.; Southwest Pacific; Major H. W. Cummings, Greenfield, Mass.; Africa; Major B. H. Bennett, Washington, D. C.; Australia New Guinea; Capt. A. J. Gantz, Greenfield, Iowa; Central Pacific. Seated left to right: Major R. C. Page, Carmel, N. Y., chief Professional Services AAF, Washington, D. C.; Major F. L. Spann, Fort Worth, Texas, chief of Professional Standards Branch, Professional Services; Major P. P. Leone, Philadelphia, former registrar, Surgeons Division.

ARMY AWARDS AND COMMENDATIONS

Major Clarence S. Livingood

Major Clarence S. Livingood, formerly of Philadelphia, has been awarded the Bronze Star Medal with a citation from the Commanding General for some as yet unpublished work which cannot be described because of censorship requirements. The citation reads "for meritorious service in connection with military operations against the enemy to provide information which would obviate the extension of this disabling condition in American troops. His work reflected great credit on himself and on the Medical Department." Dr. Livingood graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1936 and entered the service Feb. 15, 1941.

Captain George R. Conner

Capt. George R. Conner, formerly of Kirksville, Mo., was recently awarded the Soldier's Medal. The citation accompanying the award reads: "When a plane hit an obstruction and crashed during a take-off on June 14, 1944 in the Far East,

who were then removed to a hospital. The complete disregard for personal safety displayed by them reflects great credit on themselves and the military service." Dr. Conner graduated from the University of Louisville School of Medicine in 1936 and entered the service Aug. 10, 1942.

Captain Harold C. Rosenthal

Capt. Harold C. Rosenthal, formerly of Poughkeepsie, N. Y., was recently cited by Lieut. Gen. S. B. Buckner Jr., commanding officer of the Advance Command Post Headquarters, Alaska Defense Command. The citation reads: "Reports have reached me from several sources concerning the splendid service rendered by you to U. S. Army troops wounded at Attu and being evacuated in your ship. Your untiring effort and professional skill greatly alleviated the suffering of our troops during their trying voyage. I wish to convey my appreciation of your magnificent work and trust we may be so fortunate as to have the benefit of your services again in this theater." Dr. Rosenthal graduated from Cornell University Medical College, New York, in 1929 and entered the service Aug. 13, 1942.

DISTINGUISHED MEDICAL OFFICERS HONORED AT WINTER GEN- ERAL HOSPITAL

The Winter General Hospital, Topeka, Kan., has adopted the plan of naming its important clinics, buildings and streets for distinguished deceased medical officers of the Army who so far have never been honored by having their names given to buildings, general hospitals or other entities of the Medical Department U S Army. The names are selected as appropriate for the particular clinic or building. The names of the streets are those of medical officers who have become the heads of other branches of the Army. The following are the names so far selected:

The Waterhouse Medical Clinic, named for Surgeon Benjamin Waterhouse (1754-1846) of Massachusetts, who introduced vaccination in America and was first professor of medicine at Harvard.

The John Jones Surgical Clinic, named for Surgeon John Jones (1729-1891) of New York who wrote the first American medical book, founded the New York Hospital and was first professor of surgery at King's College, now Columbia University.

The Northington Roentgenological Clinic, named for Col Eugene Garland Northington (1880-1933) of Alabama, pioneer student of military roentgenology, who lost both arms and finally his life from cancer due to exposure to the rays before their danger was known to science.

The Rodriguez Dental Clinic, named for Major Fernando Emilio Rodriguez (1888-1932) of Puerto Rico, who made the first studies of the bacteriology of dental caries.

The Keen Neurosurgical Clinic named for Major Williams Keen (1837-1932) of Pennsylvania, pioneer student—with his colleagues Acting Assistant Surgeons Silas Weir Mitchell and George Reed Morehouse—of gunshot wounds of nerves and one of the few medical officers who served in both the Civil War and the first world war.

The Rush Neuropsychiatric Clinic, named for Surgeon General Benjamin Rush (1745-1813) of Pennsylvania, author of the first American book on insanity, the only systematic American treatise on the subject before 1883, signer of the Declaration of Independence and founder of the University of Pennsylvania.

The Shippen Clinic for Women named for Director General William Shippen Jr (1736-1808) of Pennsylvania first teacher of obstetrics in America, first professor of surgery in America and founder of the University of Pennsylvania.

The Woodward Laboratory, named for Lieut Col Joseph Janvier Woodward (1833-1884) of Pennsylvania, pioneer in photomicrography, eminent anthropologist and President of the American Medical Association.

The names of other important clinics, buildings and streets after distinguished deceased officers of the Army were published in THE JOURNAL, July 24, 1943, page 878.

AVIATION MEDICAL EXAMINERS

Graduation exercises for a class of medical officers who have successfully completed the Aviation Medical Examiners Course were held October 13 at the School of Aviation Medicine Randolph Field Texas. The graduation address was made by Brig Gen Aubrey Hornsby, chief of staff, AAF Central Flying Training Command, Randolph Field Texas. Presentation of the diplomas was made by Brig Gen Eugen G Reinartz, school commandant.

MEDICAL ADMINISTRATIVE CORPS OFFICER HONORED

Lieut. Ralph H Major Jr M A C formerly of Kansas City Mo aide de camp to General Hume in Italy, has been awarded the Cross of War for Military Valor by the Italian government. The presentation was made by Gen Roberto Benevenga, who was Italian military commander of Rome at the time of the Allied entry last June. The citation declared that Lieutenant Major has 'shown great devotion to duty under shell fire in connection with the capture and administration of the city of

Rome.' Last June Lieutenant Major was presented with the Magistral Cross of the Sovereign Military Order of Malta by Prince Ludovico Chigi Albani, grand master of the famous order of knighthood, which was founded in the twelfth century.

WOMEN'S ARMY CORPS PERSONNEL MAY BE ASSIGNED TO SANITARY CORPS

According to a recent release from the Sixth Service Command, Chicago, provisions of section X, Circular No 333, War Department, 1944, as far as they pertain to bacteriologists, biochemists and serologists, apply to enlisted women of the Women's Army Corps. Such personnel may be appointed second lieutenants in the Women's Army Corps for assignment and immediate detail in the Sanitary Corps. Officers appointed under this authority who later prove unsatisfactory are subject to the provisions of AR 605-230. They may be reassigned within the Medical Department. Under no condition will officers so appointed be reassigned outside the Medical Department.

PROMOTION AND NEW ASSIGNMENT FOR COLONEL PADEN

Lieut Col Paul A Padon, Cleveland, former director, Military Personnel Division, has been promoted to colonel and assigned as chief of the Personnel Service, Office of the Surgeon General, relieving Col J R Hudnall, who has been assigned as executive officer of Walter Reed General Hospital, Washington, D C. Colonel Padon has been in the Office of the Surgeon General since 1941, where he was first executive officer in the Military Personnel Division, becoming director in 1943. He graduated from the University of Tennessee College of Medicine Memphis, in 1932 and entered the service in 1934. Prior to coming to the Office of the Surgeon General, Colonel Padon was executive officer of the Station Hospital at Fort Riley, Kansas.

COLONEL ASH APPOINTED DIRECTOR OF ARMY INSTITUTE OF PATHOLOGY

Col James E Ash has been appointed director of the Army Institute of Pathology, Army Medical Museum. His title was formerly that of curator. He recently made an extended trip through the North African and other theaters of war in the interests of the Museum and Medical Arts Services. The museum is undertaking to supply all medical schools in the United States and Canada with material for research and training in tropical diseases. Lieut Col Baldum Lucke, who was acting curator during the absence of Colonel Ash, has been named deputy director.

ARMY DENTAL CORPS CONFERENCE

Dental surgeons representing the twelve major Army Air Force commands met in conference recently at the headquarters of the Second Army Air Force, Colorado Springs. The conference planned and guided by Col George R Kennebeck, D C Chief of the Dental Branch, Professional Service Division of the Air Surgeon's Office, and his assistant, Lieut Col Raymond C Turk D C, marks the first such event for Army Air Forces command dental surgeons.

MENTAL HYGIENE COMMITTEE HONORS GENERAL KIRK

The National Committee for Mental Hygiene has elected Major Gen Norman T Kirk, Surgeon General of the Army, as one of its six new members in recognition of his "unusual awareness of the importance of skilled psychiatric treatment in the Army."

HEADS SIXTH SERVICE COMMAND

Brig Gen Russel B Reynolds was recently appointed to succeed Major Gen R S Aurand as commanding general, Sixth Service Command. General Aurand's new assignment has not as yet been made public.

NAVY

PHYSICAL TRAINING ROUTINE ORDERED
IN NAVAL HOSPITALS

Vice Admiral Ross T McIntire, Surgeon General of the Navy, set in operation recently a system of organized physical training for patients in all continental naval hospitals and convalescent hospitals. The program, established under the Rehabilitation Branch Professional Division, Bureau of Medicine and Surgery, calls for "physical exercise of graded intensity" for patients to minimize "the deterioration in physical fitness which accompanies confinement to bed and thus reduce the number of sick days. Physical training thus becomes part of the daily naval hospital routine and of the general treatment plan. Exercise for individual patients will, however, be confined to activities which the responsible medical officer deems appropriate and will not exceed limitations set by him.

To facilitate assignment of patients to appropriate physical training, patients will be classified in the following groups: (1) Ambulant—no limitations on physical activity, (2) Ambulant but with stated restrictions on physical activity, (3) Confined to ward, (4) Confined to bed, (5) No activity. This phase of the Navy's rehabilitation program will be carried on under the command of medical officers by physical training officers graduated from the school established recently at the Naval Training Center, Sampson, N. Y. The first group completed the course on October 21 and subsequent groups will follow at weekly intervals. Personnel selected for this work by the Bureau of Naval Personnel majored in physical education in civil life and in many instances had experience in corrective exercises. Their indoctrination includes many of the features of a "refresher course" in physical education. To insure further uniformity in their activities each physical training officer is furnished a manual of carefully selected graded physical activities satisfactory to the Bureau of Medicine and Surgery which may be followed without interruption when a patient is transferred from one hospital to another.

Complements of physical training personnel who come under the cognizance of the Bureau of Naval Personnel but who are under the command of medical officers in command will be assigned to hospitals on an approximate basis of one officer to 1,000 patients and one specialist (A) to each 100 patients.

NAVY NEEDS 3,000 DOCTORS

Vice Admiral McIntire, who is chief of the Bureau of Medicine and Surgery, stated recently that 3,000 more physicians will be required by the Navy because personnel expansion and intensification of naval operations in the Pacific area has precipitated a grave shortage of medical officers. Admiral McIntire told Mr. Paul V. McNutt, chairman of the War Manpower Commission, that "with less than 13,000 medical officers on active duty in the Navy the procurement of at least 3,000 more as soon as possible is imperative."

The Army will fill its future requirements for military physicians from sources now available and therefore will not require future certification of availability of additional physicians from the Procurement and Assignment Service of the War Manpower Commission.

THE NAVY'S REHABILITATION PROGRAM

Vice Admiral Ross T. McIntire, surgeon general of the Navy, recently stated that "proper rehabilitation starts the day a man is wounded or breaks down." The Navy, therefore, has developed a broad program which involves a number of new ideas and is showing bright promise. "No man is so handicapped," the surgeon general said, "that he cannot become a useful citizen. So far as it is in the Navy's power, no disabled man will be returned to his community without being well equipped physically and psychologically. Whatever has happened, the disabled man is taught that he still has a valuable place to fill in the world. The chaplains who play a valued part in rehabilitation do much to replace despair and bitterness with hope and a healthy, optimistic outlook."

In this counterattack on disability encouraging victories are being won. There are very few men who have been blinded

In the Philadelphia Naval Hospital, where the blind ultimately are brought for training, there are not more than a score of these patients including men blinded by the sort of mishaps common in civilian life. They are trained to live a full and normal life, trained to take up civilian status with assurance. Highly encouraging work also is being done with the deaf. Excellent procedures have been worked out in the treatment of amputations and the training of amputees. If a man has lost an arm or a leg a plastic substitute exactly suited to his needs is made in the hospital by skilled craftsmen working in constant collaboration with the surgeons. It is routine that these men learn to drive an automobile and to dance. A great many are permitted to return to military duty. Others go into civilian life at trades learned while they are recuperating.

OFFICIAL NAVAL MEDICAL HISTORY
OF THE WAR

Capt. Louis H. Roddis (MC), USN, twice editor of the *Naval Medical Bulletin* reported for duty at the Bureau of Medicine and Surgery October 30 and has been made responsible for the preparation of the official naval medical history of the war. He recently completed thirty-one years of naval service.

NAVY AWARDS AND COMMENDATIONS

Lieutenant John E. Stewart

The Legion of Merit medal was recently awarded to Lieut. John E. Stewart, formerly of Juneau, Alaska. The citation reads: "For exceptionally meritorious conduct in the performance of outstanding services to the government of the United States as a medical officer during action against enemy Japanese forces on Tarawa Atoll, Gilbert Islands, Nov. 20, 1943. Although hampered by heavy enemy antiaircraft gun, machine gun and sniper fire, at extreme risk of his own life, he made his way to the wounded men and administered aid to them and displayed marked ingenuity in utilizing rubber boats to convey the wounded men through the surf. On November 22 he volunteered to take six corpsmen to an area of heavy fighting and under heavy enemy machine gun fire he maintained an aid station under extremely difficult and dangerous conditions. Through his resourcefulness in the use of an amphibian tractor for the evacuation of wounded, and through his courage, endurance and devotion to duty, many lives were saved that might otherwise have been lost. His conduct throughout was in keeping with the highest traditions of the naval services." Dr. Stewart graduated from Harvard Medical School, Boston, in 1941 and entered the service in September 1942.

Lieutenant Commander Tracy D. Cuttle

Lieut. Comdr. Tracy D. Cuttle, formerly of Philadelphia, has been awarded the Bronze Star Medal "for meritorious service while serving as senior medical officer of a tank landing ship operating in the Solomon Islands area from August 1943 to April 1944. Lieutenant Commander Cuttle, by his highly intelligent planning, professional ability, initiative and untiring efforts was largely responsible for equipping and training his own and other tank landing ships so that the medical service of these vessels was greatly improved, which undoubtedly resulted in the saving of many lives. The improvements were performed under adverse circumstances when equipment was difficult to obtain and numerous improvisations were necessary. His accomplishments were of inestimable value and his conduct and devotion to duty throughout were in keeping with the highest traditions of the United States Naval Service." Dr. Cuttle graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1935. He entered the service in 1940.

Captain George B. Dowling

The Distinguished Service Medal was recently awarded to Capt. George B. Dowling, formerly of Washington, D. C. His citation reads: "For exceptionally meritorious service to the government in a duty of great responsibility, as staff medical

officer of a task force of United States Naval Forces in Europe, during the period Nov 29, 1943 to July 20 1944 Captain Dowling, by his part in the planning for an operation of the system of evacuation of the wounded from the continent to the United Kingdom by LSTs has made a significant contribution to the war effort. His experience, ability, wisdom and energy were invaluable in the solution of the many intricate problems involved. The personal and enthusiastic assistance rendered by Captain Dowling in every undertaking of this important task resulted in the ameliorating of much suffering and in the saving of many lives." Dr Dowling graduated from George Washington University Medical School, Washington D C, in 1917 and was appointed to the Navy in the same year.

Commander Jasper L Custer

The Bronze Star Medal was recently awarded to Comdr Jasper L Custer, formerly of Shreveport, La. The citation accompanying the award read 'For meritorious performance of duty as Senior Medical Officer of the U S S *Block Island* when that vessel was sunk by enemy action on May 29, 1944. Commander J L Custer unhesitatingly went to the aid of a man pinned between the wreckage of the port forward catwalk and the ship's side and gave what medical aid and comfort was possible while attempts were being made to free him. After it became evident that it would be necessary to amputate the man's leg if he was to be freed before the ship sank, Commander Custer performed the operation under extremely hazardous and unfavorable conditions and succeeded

in releasing the man in time to remove him from the rapidly sinking ship. Commander J L Custer's calm and efficient performance of duty in the face of great danger was an inspiration to the entire crew and was in keeping with the highest tradition of the United States Naval Service." Dr Custer graduated from the University of Texas Medical Branch, Galveston, in 1927 and entered the service April 6, 1942.

Lieutenant Mark W Wolcott

The Air Medal was recently awarded to Lieut Mark W Wolcott, formerly of Philadelphia, for "meritorious achievement in aerial flight as crew member of an R4D transport plane attached to the South Pacific Air Transport Command from July 15 to 25, 1943. When his craft was unable to land on the densely overgrown jungle terrain while transporting urgently needed supplies to our forces on New Georgia Island, Lieutenant Wolcott skilfully performed his duties and rendered invaluable assistance to his pilot in accurately dropping the cargo as the unarmed plane flew in at terrific speed and at tree top level to avoid intense enemy antiaircraft fire and aerial opposition, making several hazardous runs on the targets to complete the mission and frequently returning to base without the protection of covering planes. Lieutenant Wolcott's cool courage and unwavering devotion to duty under extremely difficult conditions contributed materially to the success of these vital missions and were in keeping with the highest traditions of the U S Naval Service." Dr Wolcott graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1941 and entered the service July 15, 1942.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

U S Naval Hospital, San Diego, Calif. Surgery of the Chest. Dr Leo Eloesser, November 30.

U S Naval Hospital, Philadelphia. Recent Physiologic and Pharmacologic Studies Bearing on Respiration, Dr Carl Schmidt, December 1. The Common Cold, Influenza, Dr Hobart A Reimann, December 15.

Critch General Hospital, Cleveland. Bone Grafting, Dr James A. Dickson, December 12.

Camp McCoy, Wisconsin. Endocrinology, Dr Elmer L Sevringhaus, November 29. Virus and Rickettsial Diseases, Dr Marcos Fernan-Nunez, December 13.

U S Naval Hospital, Great Lakes, Ill. Diagnosis and Treatment of Acute Suppurative Meningitis. Dr Paul S Rhoads, December 5. The Physiology of Respiration as It Affects Thoracic Surgery, Dr Ralph B Bettman, December 19.

THE NETHERLANDS FACING FAMINE AND EPIDEMICS

The Netherlands Information Bureau reports that the Dutch people are now faced with a dangerously rising death rate caused by the shortage of food and fuel. One of the most alarming symptoms of the people's lowered resistance is the increase in tuberculosis, a direct cause of which is malnutrition. At the beginning of this month the diet for the inhabitants of the larger cities dropped to less than 900 calories a day. By international standards a person who sits quietly all day engaging in no activities whatever requires a minimum of 1,200 calories each day, while any one who does a normal day's work needs from 2,500 to 4,000 calories. Margarine and butter supplies were completely exhausted by November 1 in Amsterdam and Haarlem; there is no flour for the baking of bread while in other cities all flour will be gone soon.

Unless the cities of the Netherlands are liberated within a short time, the disaster will assume gigantic proportions. Owing to the complete lack of fuel, the pumping stations, which supply the Dutch people with their drinking water, will soon cease to operate. Holland's intricate sewerage system will also come to a standstill and an outbreak of epidemics of the worst sort may be expected.

PLACEMENT PROGRAM FOR VETERANS

Northrop Aircraft, Inc., Hawthorne, Calif., recently developed a placement program by which veterans of this war, particularly those with physical handicaps, may be intelligently moved into industry. The Northrop placement program begins at Birmingham General Hospital at Van Nuys, Calif., where the company has established an airplane production department. It contains machines, tools and all equipment necessary for light metal shop work. Convalescents, nearly all of whom are overseas casualties, are given a short training course and then start on actual production, for which they are paid standard shop rates. When these men are discharged for return to civilian life they are encouraged to take employment at the main Northrop plant. On recovery the veteran who is discharged is adjusted to a special type of work and readily fits into this work. This is primarily for the physically handicapped or injured. Dr Harold B Dye, chief surgeon at Northrop Aircraft, Inc., stated that the same basic plan could be worked out for the mentally handicapped. Agencies should be established in connection with hospitals to assure a round peg being placed in a round hole. The United States Employment Service is of assistance in finding work for veterans but is not able to approach the subject from the standpoint of specialized work for the physically and mentally handicapped.

RED CROSS SENDS PENICILLIN BY AIR FOR PRISONERS OF WAR IN GERMANY

The American Red Cross has sent 5,000 tubes of penicillin by air express to the International Red Cross Committee in Geneva to be used for American prisoners of war held by Germany. The Red Cross plans additional shipments of medicines and medical supplies for prisoners of war. The International Committee has been asked to keep the prison camp leaders informed of the medicines available in the stocks held in Geneva for their use and to suggest that the leaders not allow camp stocks to become depleted before reordering.

Regular shipments of Red Cross first aid kits intended for use when doctors are not available have been made to the prison camps in Germany. Bulk shipments of medicine and medical supplies also have been made to supplement those provided by German military authorities for the care of sick and wounded prisoners of war.

ORGANIZATION SECTION

Official Notes

THE 1945 ANNUAL SESSION

The Ninety-Fifth Annual Session of the American Medical Association will be held in Philadelphia June 18 to 22, 1945. This session was originally scheduled to be held in New York June 11 to 15, but because of untoward conditions growing out of the war emergency it was found that needed facilities would not be available in that city.

A very cordial invitation has been extended to the Association by the Philadelphia County Medical Society to hold the 1945 session in that city. The Philadelphia Convention and Tourists Bureau, the Hotel Association, those concerned with the operation of transportation facilities and other civic groups have given assurances that everything possible will be done to contribute to the success of a meeting in Philadelphia. Final arrangements are being made as rapidly as possible.

Hotel Reservations

Hotel reservations will be made through a central office in Philadelphia. It is highly desirable that reservations be made as early as possible. Those who expect to attend the Philadelphia session are urgently requested to refrain from making reservations in more than one hotel. In numerous instances at the annual session held in Chicago in 1944, and at other sessions previously held, individual physicians have made reservations at two or three hotels and on arrival at the place of meeting have completed their reservations at one hotel and failed to cancel other reservations. The result has been that many physicians have found it impossible to secure accommodations. If this practice is persisted in it will become increasingly difficult for the Association to find a satisfactory place of meeting.

At the Chicago session several hotels had a large number of reservations which they had made in good faith only to find that multiple reservations made by individuals which were not needed, were not canceled, and the result was that the hotels had vacant accommodations, which after a short time were given over to persons who were not concerned with the annual session of the American Medical Association.

Washington Letter

(From a Special Correspondent)

Nov 20 1944

Medical Stand on Extension of Social Security Considered

A determined move is under way in Congress for extension of social security. It is expected that extension of social security will ultimately be achieved and, when this happens social security taxes must go up. Another argument, not connected with the extension issue, is now raging on the question of doubling social security taxes next year on both employers and employees. More than 50 million people are affected. The administration favors the doubling, but House and Senate leaders close to the subject are against it as in several previous years. The "pro" argument is that the terms of the Social Security law should be carried out now because so many people are making money. The "against" argument is that so much money has already been earmarked for future social security payments on the basis of benefits under the present law, that it would be unnecessary and unwise to increase the tax burden.

Senator Arthur Vandenberg, Republican of Michigan, made his fourth annual move to freeze the rate at the present 1 per cent level. He argues that if existing pay roll rates the social security reserve (now estimated at more than 6 billion dollars in government bonds) is from eight to twelve times the contemplated annual drain on the fund in the next five years.

House and Senate tax committee leaders have tentatively moved to compromise the 1 per cent tax increase now scheduled to take effect automatically January 2. Instead of the 2 per

cent doubled rate on workers and employers starting New Year's day, they propose to spread the increase over two years. Under the plan, still in renegotiation, the tax would be moved up to 1.5 per cent in January 1945 and would not reach the full 2 per cent rate until January 1946.

President Asks Year's Compulsory Training for Young Persons

President Roosevelt told his latest White House press conference that he hopes Congress acts this winter on legislation requiring the youth of the nation to give a year's service to the government. Seemingly aware of opposition of both Protestant and Catholic church leaders, the President did not commit himself on whether compulsory training should be military. The President recalled physical benefits gained by youths who went through the Civilian Conservation Corps program. He pointed out that the CCC boys did not have military training but benefited greatly from their experience. He said that a universal training program would give the nation a large number of young people trained to defend the country in the event of future wars. The Army favors compulsory training to make it possible to mobilize four million men overnight, and several bills along this line have been introduced in Congress.

Service Chiefs Ask for Increased Blood Donations

An appeal for increased blood donations was made here by Vice Admiral Ross T. McIntire, Surgeon General of the Navy, and Major Gen. Norman T. Kirk, Surgeon General of the Army. Increasing casualties in both Europe and the South Pacific are necessitating air shipments of whole blood to both battle fronts. The service chiefs have pointed out that among those who have given blood are a number of men in service who themselves have faced death and suffered wounds. Many World War I veterans, they added, have been consistent blood donors. Whole blood is shipped daily from Washington and New York to Europe, and regular shipments go from the West Coast to the South Pacific. A new method had to be devised to keep blood fresh on its long journey via Naval Air Transport Service from San Francisco to Pearl Harbor and then to island bases.

Army Medical Research Board to Continue in Peace

Brig Gen James S. Simmons, chief of the preventive medicine service in the Office of the Surgeon General, U. S. Army, told the meeting of the National Academy of Sciences here that plans are being made for an Army Medical Research Board to continue in peacetime to seek ways to protect army health for better defense of the nation. Correlated with the proposed Army Medical Research Board, under present plans, would be a committee on Medical Research for developing within civilian institutions medical investigations of importance to the armed forces. The Army board would include one member of the civilian committee, which in turn would have one member from the Army board, to provide closest cooperation.

WINNEBAGO COUNTY MEDICAL SOCIETY PLAN

Edwin G Quattlebaum Jr, M D
ROCKFORD ILL

In early 1942 most members of the Winnebago County Medical Society were aware of increasing interest in medical social security. Some of the membership realized how difficult it was for the average busy physician to keep in close touch with the needs, desires and demands of the people. A committee was established to be known as a Public Relations and Planning Committee. Its major functions were

1 To keep itself posted on trends of public thought and on ways and means of meeting requests of the public for increased medical service

2 To keep the membership of the society advised as to these trends and their extent

3 Possibly to some extent to mold public opinion

The committee's membership was almost unanimously opposed to governmental administration of medical services under the Surgeon General of the U S Public Health Service or under any other individual. The committee was convinced that medical service to the American public could be increased through prepaid medical care programs in which the individual could obtain partial reimbursement by paying the premium directly out of his pocket rather than through taxation.

It soon became obvious that several fundamental principles should be kept in mind. First, the absolute right of any patient to select his own physician without any restraint, interference or pressure from any source and the right to do this at any time, should be maintained. Second, the patient-physician relationship should be carefully guarded. Third the premium should be low so as to reach the average family. It was our desire that the plan should not prepay all expenses. We wanted something similar to the automobile collision deductible policy, which meets the bulk of auto accident costs without encouraging careless driving and unwarranted claims. Moreover we believed that a total payment plan would have a tendency to influence fees. Fourth it was felt that under no circumstances should the fee be paid directly to a physician, so as to avoid any semblance of self interest or collusion between insurance carriers and physicians. The ideas were in keeping with those developed in the House of Delegates of the American Medical Association.

As time went by it became apparent that no plan yet devised met in every respect the principles listed. Throughout the country plans were beginning to be developed most of which were based on the idea of a group of physicians caring for a group of patients for an annual fee. This, to our way of thinking, interfered with the unlimited choice of physicians on the part of the patient and for that reason did not meet with our approval. Further, most of the plans developed in the beginning did not attempt to care for medical as well as surgical disabilities, and we felt that this should be attempted.

Fortunately for our community a Blue Cross plan for partial prepayment of hospital care had been organized under the able direction of Mr F F Armstrong executive secretary, and with the cooperation of the physicians and hospitals of the community, had done an outstanding job. The success of the nonprofit hospital plan in Winnebago County led us in the beginning to consider an extension of Blue Cross, to include reimbursement of medical expenses, but we learned that the hospital service could not enter the medical-surgical field until the Illinois state legislature passed an enabling act.

The county medical society authorized the committee to aid in passage of an enabling act. This procedure, of course requires time and there are dangers. The greatest danger is that unless the act is painstakingly worded it might be possible for unethical organizations to practice medicine. In any event the Illinois legislature was not to meet until January 1945.

Rather than to await passage of such an act, we began to consider commercial plans and soon discovered that we were unable to find any that attempted to meet the overall ideas we

had in mind. Fortunately, about this time we learned that one of the larger writers of accident and health insurance in this country was considering the idea of trying such a plan in a small way. As a result of this discovery our conversations with the North American Accident Insurance Company began. This organization was interested, and after considerable discussion between members of the committee and executives of this company a tentative plan was worked out. At this time the committee took to the county medical society a request for the adoption of two resolutions.

1 That the society go on record as approving the development of any prepaid medical care plan which would meet the prerequisites listed.

2 That the committee be empowered to approve the plan submitted by the North American Accident Insurance Company.

The two resolutions were adopted.

The plan submitted by the North American Accident Insurance Company is experimental, to be tried in Winnebago County only until such time as an actuarial experience can be developed which might warrant its wider use.

This particular commercial insurance company has been most cooperative. It has agreed, for example, that official advertising done would be released only after its approval by the planning committee of the Winnebago County Medical Society. It has also agreed that, if the experience in this community warrants, the plan will be rapidly liberalized. At present, unfortunately, if the plan is to be sold at low cost it is necessary that it contain some exclusions and exceptions.

The Winnebago County Medical Society has no desire to sponsor any one insurance carrier. On the contrary, it hopes that every reputable insurance carrier in the United States will see fit to sponsor and sell such plans, not only elsewhere in the country but also in this community. Just as we feel that the free choice of a physician on the part of a patient makes for better medical care, we feel that competition among insurance carriers, profit and nonprofit, is most advantageous to the public. This community, therefore, is anxious to support any plan that meets the specifications outlined and feels that, the more organizations that can be developed the more rapidly low cost prepaid medical care plans may be obtained by the public.

Briefly, the plan approved by this committee as presented by North American Accident Insurance Company is as follows.

The plan will partly reimburse the patient for medical expenses thus:

A fee of \$2 per call in the event of any disabling illness on the part of husband or wife up to 65 years of age and any dependent member of the family between the ages of 3 months and 18 years. The fee is to be paid regardless of whether the call is made in a physician's office, in a hospital or in the patient's home. The first two calls are deducted, being left to the patient to pay. In the event that the disability is due to accident, payment begins for first call. The total paid by the insurance carrier in any one illness for any one member of the family shall not exceed \$250 in any one year. The total for all children shall not exceed \$500 in any one year. The total for husband and wife shall not exceed \$500 in any one year. In the event of a surgical disability, in lieu of the \$2 per call the patient may elect to take a flat surgical fee, which fee favorably compares with fees provided in standard accident and health policies.

The premium charge for the foregoing shall be \$3 per month, less 10 per cent for an annual premium paid in advance. This provides for the entire family of husband, wife and any dependent children between the ages of 3 months and 18 years. Single persons obtain protection at proportionately lower cost.

There are other exceptions and exclusions most of which are minor, and it is sincerely hoped that the plan will be sufficiently successful from an actuarial point of view to warrant the rapid elimination of many of these minor exclusions.

It would not be fair to close this article without expressing for the committee its great appreciation of the help, courtesies and kindnesses extended to us by the American Medical Association, particularly its legal department, the National Physicians Committee for the Extension of Medical Care and representatives of local newspapers.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Changes in Health Personnel—Dr Harrison Eilers, health officer of San Luis Obispo has been appointed health officer of Long Beach, succeeding Dr Frank W Stewart, who resigned November 1. Dr Andrew M Harvey, assistant health officer, has been named acting health officer until Dr Eilers takes over his new work about January 1.

Personal—Morris A Stewart, Ph D, associate professor of parasitology, College of Agriculture, University of California, Berkeley, has returned to the university after three months spent in South America (THE JOURNAL, July 22, p 858), chiefly in Bolivia, as consulting parasitologist to the government. While there he was made honorary professor of parasitology of the Instituto Superior de Medicina Veterinaria and the Instituto Orientale de Biología.

Human Death from Rabies—A 3 year old child died in September in Albany following the bite of a rabid dog, according to *California's Health*, official bulletin of the state department of health. The dog strayed into Albany, where it was killed by a policeman after it had bitten the child. One dog bitten by the animal and 2 contacts are still under observation. The bulletin emphasizes the need for preventive measures and for the exercise of rigid control over dogs and cats in those communities where rabies is known to be present. During the past year the disease has been found in Kern, Imperial, Tulare, Kings, Fresno, Los Angeles, Monterey, Napa Contra Costa, Riverside Sacramento, San Bernardino, San Diego, San Luis Obispo, Santa Cruz, Solano, Sonoma, Stanislaus and Alameda counties. The latest area to be included is the east shore of San Francisco Bay, particularly in Berkeley, Albany, El Cerrito, Richmond and Crockett. The examination by the state laboratory of the head of a dog which had bitten a man and a woman in Berkeley proved the presence of the disease in the animal.

CONNECTICUT

Society Creates Section on Surgery—Dr Paul W Vestal, New Haven has been appointed chairman and Drs Donald B Wells, Hartford, chairman elect, and Andrew J Jackson, Waterbury, secretary-treasurer of the newly created section on surgery of the Connecticut State Medical Society.

Building Fund—At a meeting of the council of the Connecticut State Medical Society, October 10, the trustees of the society's building fund were directed to proceed at once with a fund raising program to obtain contributions for \$50 000 to provide a building for the society's headquarters. The first meeting to discuss preliminary plans was held October 25.

Statewide Peacetime Blood Bank—The council of the Connecticut State Medical Society has appointed a special committee to confer with a similar committee from the Connecticut Hospital Association to discuss a proposed plan to continue, if possible, the community blood and plasma banks that have been developed during the war. Members of the committee are Drs Ralph E Kendall, Hartford chairman, John C Leonard, Hartford, Karl T Phillips, Putnam, Arthur J Geiger, New Haven, and Irving B Akerson, Bridgeport.

DELAWARE

State Journal Has New Address—The *Delaware State Medical Journal* announces that its new address is 822 North American Building, Wilmington 7. For two and one-half years the *Journal* was located at 618 Citizens Bank Building, but the new owners of the building the North American Mutual Insurance Company, have renamed it the North American Building. The state journal now occupies larger quarters in the renamed building.

DISTRICT OF COLUMBIA

Personal—Major Alfred Golden M C who has been on duty for the past four years at the Army Medical Museum has been transferred to the division of health and sanitation Office of the Coordinator of Inter-American Affairs.

Child's Death from Rabies Called "Unique"—On November 1 a positive rabies report was issued by Dr John M Byers health officer of Prince Georges County, Md in the death of a 16 year old boy of Mount Rainier, Md, October 19. Newspapers stated that the case would be one of the most unusual in medical history if the parents' assumption is true that the boy was infected with rabies some fourteen months ago by his pet dog. The dog was taken to a hospital on Labor Day 1943 after he acted 'peculiar' and appeared to be sick. Several days later it was stated, the dog died after he had apparently strangled himself in a net at the hospital. No examination for rabies was performed. It was pointed out by the attending physician that no bite would have been necessary from the pet dog as the boy could have become infected through saliva through scratches on the skin. The physician said the boy showed no signs of any illness all the time he supposedly carried the deadly infection. He became ill suddenly October 13 was taken to George Washington University Hospital October 15 and died there four days later. In March a 65 year old woman died at Gallinger Municipal Hospital five months after being bitten by a rabid dog and in November 1943 a soldier stationed in Washington died after being infected by a dog.

ILLINOIS

Changes in Health Personnel—Ruth Sumner Ph D has been appointed acting chief of the division of public health instruction, Illinois State Department of Public Health during the leave of absence of Leona de Mare East A B, who is continuing her graduate training in health education at the University of North Carolina School of Public Health.—Dr Donaldson F Rawlings, Cairo has resigned as health officer of the Alexander-Pulaski County Health Unit to enter the U S Navy.—Dr Samuel S Reinglass, Dixon resigned as health officer of Lee County, effective October 1, to enter private practice in Canton, Ohio.

CHICAGO

Personal—Dr Howard Glenn Gardiner, Chicago has resigned as medical director of Foote Brothers Gear and Machine Corporation, effective November 20 to become associate medical director of Oldsmobile division of General Motors, Lansing, Mich.

Dr Ivy to Address Institute of Medicine—Dr Andrew C Ivy, Nathan Smith Davis professor of physiology and pharmacology, Northwestern University Medical School will deliver the presidential address at the twenty-ninth annual meeting of the Institute of Medicine of Chicago, December 5, at the Palmer House, on "Contributions to Survival on a Raft at Sea."

KANSAS

Personal—Dr Vernon M Winkle, director of the district health unit at Gering, Neb, has been named epidemiologist and assistant director of the health department of the Topeka-Shawnee Health Department. He will also be in charge of the school health services of the unit.

Graduate Medical Clinic—The fall clinic on obstetrics and pediatrics, sponsored by the Kansas Medical Society the state board of health and the University of Kansas School of Medicine, was held at the Lassen Hotel, Kansas City November 2-3. The principal speakers were Drs Julian D Boyd, associate professor of pediatrics, State University of Iowa College of Medicine, Iowa City, and M Edward Davis professor of obstetrics and gynecology, University of Chicago School of Medicine.

Jayhawker, M D—The October graduating class of the University of Kansas School of Medicine, Lawrence-Kansas City brought out the first student annual for publication by the medical class of the school. The volume is a testimonial to the members of the faculty, to the many students in all classes and to the school itself. It is replete with photographs of teachers students and school buildings. The book is a splendid tribute to the efforts of the recent graduating class. In its own defense, editorially, the class rejects the comment passed at some time during its career that it was the worst class the school had seen in thirty-one years.

Free X-Rays at State Fair—A feature of the Kansas Free Fair in Topeka this year was the offer of chest x-rays to all who cared to have them. Of 5,000 visitors at the exhibit during the week of the fair, 1,129 were given roentgenograms which disclosed 18 cases of significant tuberculosis hitherto unreported to the state board of health. Two were in persons in the age group 15-24, 8 in the age group 25-44, 3 in the age group 45-64, and 5 persons more than 65 years

of age. In addition to these eighteen patients, all of whom were referred to their family physicians, 15 persons were advised to consult their physicians because of lesions suggestive of tuberculosis and 15 others showed chest or heart conditions which warranted further examination by a physician. The public health building at the fair, which has been under the supervision of the state board of health since 1936 was devoted entirely this year to tuberculosis education. The Topeka Tuberculosis Association and the division of tuberculosis control of the state board of health cooperated.

MARYLAND

Dr Williams Reappointed—Dr Huntington Williams has been reappointed commissioner of health of Baltimore for a six year term. He has held the position since January 1933 after having first served as director of health from Oct 1 1931.

Society News—The Baltimore City Medical Society was addressed November 17 by Dr Edward M Hanrahan, Baltimore, on "Indications for and Procedures Used in Breast Plastic Operations" and Col Thomas Fitz-Hugh, M C. A Medical Officer's Experiences in a Jungle Theater of Operations."

University News—The department of pharmacology of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, has received a gift of \$4000 from the Ohio Chemical and Manufacturing Company of Cleveland to establish a fellowship for the study of volatile anesthetics, especially "propethylene," under the direction of John C Krantz Jr, Ph D, professor of pharmacology.

MASSACHUSETTS

Licenses Revoked—At a meeting of the Massachusetts Board of Registration in Medicine, September 13, the license to practice medicine of Dr Mary C Bolger, Worcester was revoked because of violation of her probationary period as of Feb 10, 1942 and the license of Dr Don D Cornell, Pilcher, Okla formerly of Boston, because of the violation of the Harrison Narcotic Act.

John Downing Named Professor at Tufts—Dr John G Downing has been appointed professor of dermatology and syphilology at Tufts College Medical School, Boston and chief of the department of dermatology and syphilology at Boston City Hospital, the *Harvard Medical Alumni Bulletin* for October announced. Dr Downing is also professor of dermatology at Boston University School of Medicine and dermatologist in chief at the Massachusetts Memorial Hospitals.

MONTANA

Osteopaths Defeated in Montana—On November 7 the Montana voters defeated an Initiative, Number 48 a bill that would have given Montana osteopaths "unlimited surgical rights" and would have defined osteopathy as a branch of medicine with its own ruling board. The bill was defeated almost two to one. Credit in the defeat of the bill is ascribed to the Public Health League of Montana a recently formed group with offices in Helena including dentists of the state, the Montana Hospital Association the Catholic Hospital Association Montana State Medical Association Montana State Nurses Association Optometric Association Hospital Service Association of Montana Montana Tuberculosis Association state division of the Field Army, pharmacists of the state and many other interested groups. Mr Joseph L Markham Butte newspaperman was designated campaign manager against the bill and the Montana State Medical Association was represented by its officers and a special seven man committee.

NEBRASKA

Ninety-Two Years of Age—Dr John A Waggener Humboldt observed his ninety-second birthday in October. According to the *Nebraska State Medical Journal* Dr Waggener observed the day attending to his practice as usual.

NEVADA

State Medical Election—Dr Moreton I Thorpe Reno secretary of the Nevada State Medical Association, writes that at the recent meeting of the state medical association Dr Daniel J Hurley, Eureka was reelected president. Dr Hurley had been elected in 1942 to take office as president but soon afterward he was called into service leaving his term unfilled. Dr Lemuel R Brigman, Reno, was at the same time president elect, so he automatically assumed the office in Dr Hurley's place in 1942 and then in his own right became president in 1943 causing

his presidency to run two years, through the unfilled term of Dr Hurley and his own. These circumstances left Dr John R McDaniel Jr, Las Vegas, as president-elect. He was to take office in 1942 as president, but when he was called into service the association chose Dr Hurley. Dr Thorpe points out that two president elects were called into service at almost the same time. Dr Hurley is now president and Dr McDaniel president-elect.

NEW YORK

Memorial to Physician—A campaign is under way in Pavilion to collect funds to create a Dr Sweeting Memorial Fund in honor of the late Dr Sherman C Sweeting, who practiced in the community for more than fifty years. The memorial will honor the physician and be used as Pavilion's contribution to the campaign under way to build in Batavia a new Genesee Memorial Hospital.

New Consultant Named for Silicosis—Dr Edward G Whipple, Rochester, has been appointed a special consultant to the state department of labor on dust diseases, notably silicosis, to succeed the late Dr John J Lloyd, Rochester. Dr Whipple will serve with Drs Edgar Mayer and J Burns Amberson Jr, New York on the commission, which was established by the state legislature some years ago. Dr Whipple will have charge of the Buffalo Rochester districts.

Paul Lembcke to Direct Temporary Commission of Medical Care—Dr Paul A Lembcke, Rochester district number 4 health officer, under leave of absence granted by the New York State Department of Health, has been appointed director of study for the New York State Temporary Commission of Medical Care, according to the *Rochester Democrat and Chronicle*. Dr Lembcke served as state epidemiologist in 1939. Offices of the commission have been opened in the Terminal Building Rochester.

Teaching Day on Rheumatic Fever—November 30 has been designated teaching day on rheumatic fever and rheumatic heart disease at Syracuse University College of Medicine. Among the speakers will be

Dr T Duckett Jones Boston Etiology, Epidemiology and Diagnosis of Rheumatic Fever and Rheumatic Heart Disease
Dr Albert D Kaiser Rochester Treatment of Rheumatic Fever
Dr Homer F Swift New York Prevention of Recurrences in the Known Rheumatic Patient
Dr David D Rustein Albany Need for a Public Health Program for the Care of the Rheumatic Child

A dinner meeting will be addressed by Dr Brewster C Doust, professor of pediatrics at Syracuse. Among the agencies sponsoring the day's program will be Cayuga, Cortland Onondaga and Oswego county medical societies the state medical society, the state department of health and the university.

New York City

License Restored—The license to practice medicine of Dr Millicent Morden Brooklyn which had been suspended for one year, was reinstated by the state education department on September 22.

Max Bergmann Dies—Max Bergmann, Ph D, a member of the Rockefeller Institute for Medical Research and prominent for his work in organic chemistry, died at Mount Sinai Hospital November 7, aged 58.

Medical Bequest—Under the will of the late Henry R Ickelheimer, a private banker, Cornell University will receive \$25,000 for cancer research, according to *Science*. There is also a provision for \$42,500 for Mount Sinai Hospital.

Personal—Dr Andrew J Warren who has been associated with the International Health Division of the Rockefeller Foundation since 1921, has been appointed assistant director.—Dr William H Kahrs was recently guest of honor in celebration of his completion of fifty years in the practice of medicine.

The Janeway Lectures—Dr Otto Loewi, research professor of pharmacology New York University College of Medicine, gave the Edward Gamaliel Janeway lectures at Mount Sinai Hospital, November 13 on 'Aspects of the Transmission of the Nervous Impulse' and one November 15 on 'Theoretical and Clinical Implications'.

OHIO

Personal—Milton J Foter Ph D, has recently been appointed head of the department of bacteriologic research of the William S Merrell Company Cincinnati.—Dr James Howard Holmes Toledo, has been appointed a member of the Ohio Public Health Council to fill the unexpired term of the late Dr Ward D Coffman Zanesville which will end June 30 1950.—Dr Johnson S Hunter Jackson, recently completed fifty years in the practice of medicine.

Physicians Honored—A portrait of the late Dr Asa Brainerd Isham who died in 1912, one of the founders of the Cincinnati General Hospital and a former president of the Cincinnati Academy of Medicine, was recently presented to the hospital by the children of Dr Isham—Drs Charles I Thomas and William E Brumer received the distinguished service award of the Cleveland Community Fund for outstanding work in the field of sight restoration

Fifty Thousand Dollars for Study on Proteins—Swift & Company, Chicago, has given a special grant of \$50,000 to the University of Cincinnati for a five year research project on proteins and their role in rehabilitating persons disabled by nutritional deficiencies. The study is to be carried on at the Hillman Hospital, Birmingham, Ala under the direction of Dr Tom D Spies associate professor of medicine, University of Cincinnati College of Medicine. Since 1936 Dr Spies has been directing work in this field both at the university and at the Hillman Hospital, where he is director of the Nutrition Clinic

PENNSYLVANIA

Lester Perry Appointed Executive Secretary of State Society—Mr Lester H Perry, A.B., since 1934 manager of sessions and exhibits of the Medical Society of the State of Pennsylvania, has been appointed executive secretary. Mr Perry, who joined the state medical society after serving as executive secretary of the Allegheny County Medical Society, graduated at the University of Pittsburgh in 1925

Annual Postgraduate Day—The Harrisburg Academy of Medicine held its annual postgraduate day in Harrisburg, November 16. The program constituted a seminar by the following members of the faculty of Ohio State University College of Medicine Columbus

Laurence H Snyder ScD. Importance of the Hereditary Background in Medical Diagnosis Prognosis Prevention and Treatment and Current Medical Significance of the Blood Groups with Special Reference to the Rh Factor

Dr George M Curtis Diseases of the Parathyroid Glands and Their Management and Surgical Considerations in Splenic Disease

Dr Charles A Doan Differential Diagnosis and Treatment of the Anemic States and Increasing Significance of the Pathologic Physiology of the Spleen in Clinical Medicine

Philadelphia

Hospital News—The name of the National Stomach Hospital has been changed to the Physicians and Surgeons Hospital, effective October 15

Personal—Dr William B Griggs, who has completed fifty years in the practice of medicine, was guest of honor at a dinner November 1 given by members of the staffs of St Luke's and Children's Medical Center and the Women's Homeopathic Hospital

The Pancoast Memorial Lecture—The fourth Henry K Pancoast Memorial Lecture was presented before the Philadelphia Roentgen Ray Society and the College of Physicians of Philadelphia November 2 by Dr Edward B Benedict Boston. Dr Benedict's subject was "The Correlation of Gastroscopic, Roentgenologic and Pathologic Findings in Lesions Involving the Stomach"

SOUTH DAKOTA

Personal—Dr Clarence L Sherwood, Madison, has been appointed to the state board of health to fill the unexpired term of the late Dr James B Vaughn, according to the *Journal Lancet*—Dr Frank W Haas, assistant superintendent of the Yankton State Hospital at Yankton, has been appointed by the governor to the commission for control of feebleminded succeeding the late Dr George S Adams

TEXAS

Dr Painter Named Acting President of University of Texas—Theophilus S Painter, ScD, research professor of zoology University of Texas, Austin, has been made acting president of the university

Changes in Hospital Superintendents—Included among the recent changes in hospital superintendents of the state hospitals are the following: Dr Roy Cameron Sloan assistant superintendent Terrell State Hospital Terrell superintendent, to succeed Dr William Thomas who retired September 15, Dr Bruce Allison assistant superintendent Wichita Falls State Hospital Wichita Falls to succeed Dr Monroe A Beckman at the Abilene State Hospital Abilene, effective September 1 and Dr David McCullough assistant superintendent of the State Tuberculosis Sanatorium, Sanatorium, superintendent of the Kerrville State Sanatorium Kerrville. Dr McCullough succeeds Dr Henry Y Swazze who resigned September 1 to enter private practice

VIRGINIA

Personal—Thomas Gordon Bennett Ph.D. formerly of the U S Public Health Service and once superintendent of schools for Calvert and Queen Anne's counties, Md has been appointed consultant in health education to the Virginia Department of Education

State Medical Election—Dr Julian L Rawls Norfolk was named president-elect of the Medical Society of Virginia at its meeting in October and Dr Henry B Mulholland, Charlottesville, was inducted into the presidency. Miss Agnes V Edwards 1200 East Clay Street, Richmond 19, is the secretary. The 1945 session will be held in Roanoke

Changes in Health Personnel—Dr Glenn H Baird has resigned as venereal disease control officer of the Richmond City Health Department to become health officer of the Smyth-Washington-Bristol Health District, with headquarters in Abingdon—Dr William B Bailey, Montgomery, W Va has been appointed health director for Norfolk and Princess Anne counties—Dr Donald K Freedman, U S Public Health Service, has been named health officer of district number 5, Williamsburg, to succeed Dr William W Fuller, who resigned to enter the armed forces, effective November 1

WASHINGTON

Hospital News—On October 15 the cornerstone of the new Doctors Hospital, Seattle, was laid at special ceremonies of the board of trustees of the King County Medical Service Corporation (THE JOURNAL, Dec 18, 1943 p 1059)

Personal—Dr Herbert A Perry, assistant superintendent of the Eastern State Hospital, Medical Lake, has been appointed superintendent. He succeeds Dr Marinus W Conway, who will enter private practice after serving in the position for eleven years—Dr John H O Shea, Spokane, was guest of honor at a banquet at the Davenport Hotel August 10, in recognition of his completion of thirty-five years with the Spokane fire department—Dr Edward B Riley, Aberdeen has been appointed temporary coroner of Grays Harbor County to succeed Dr Joseph H Fitz, Montesano, resigned

WEST VIRGINIA

State Association Acts to Remove Politics from Health Program—At a meeting November 9 the council of the West Virginia State Medical Association unanimously adopted a legislative program providing for

The appointment by the governor of a state health commissioner from a list of three names or more to be submitted by the council of the West Virginia State Medical Association

The appointment of medical members of the Public Health Council from a panel of three names for each position to be filled to be submitted to the governor by the council of the West Virginia State Medical Association

The appointment of superintendents of state eleemosynary institutions from a list of names to be submitted to the governor by the Public Health Council

The council recommended that the Barboursville unit of the Weston State Hospital be reestablished as a unit of the Huntington State Hospital, that \$100,000 be appropriated for each year of the biennium for cancer control and that the arrangement with the Medical College of Virginia Richmond, for the admittance of twenty students annually from the two year medical school at West Virginia University Morgantown, be continued. Both committees and the council devoted a good deal of time to the consideration of an enabling act in connection with the operation of hospital-medical surgical plans in this state. The present act passed at the 1943 session of the legislature becomes inoperative Feb 28 1945. Solution of the problem was left to the legislative committee, which was instructed to consult with similar committees from the hospitals and hospital-medical service groups in drafting a bill to be introduced in the legislature in January. The association has already approved a basic contract for use by component societies in connection with the establishment of medical-surgical service plans over the state. The council also approved in principle the extension of Farm Security Administration service plans to provide medical and hospital service to certain families in the low income group in every part of the state. Sixteen such plans have already been established. The council recommended the establishment of a department of public health at West Virginia University and approved the university's plan to ask for an appropriation for a new building for the two year school of medicine. Approval was also given to the following items in the state health department's legislative program: antepartum serologic examination for syphilis transfer of the crippled children's division from the department of public assistance to the state health department transfer of the supervision of the superintendents of the state eleemosynary institutions from the board

of control to the public health council, creation of a dental hygiene division, increase in the salary of the state health commissioner and construction of a separate building on state property near the capitol to house all divisions of the state health department

GENERAL

Examinations in Otolaryngology—The American Board of Otolaryngology will conduct examinations at the Waldorf-Astoria, New York, June 5-8, and at the Palmer House, Chicago, October 3-6

National Public Health Nursing Day—The first National Public Health Nursing Day will be held throughout the country on January 26. The theme of the observance will be "Know Your Public Health Nurse—Who She Is, What She Does." In charge of details is the National Organization for Public Health Nursing, Inc., 1790 Broadway, New York 19

1945 Public Health Meeting—The executive board of the American Public Health Association announces that the third wartime conference and seventy-fourth annual meeting, and meetings of related organizations, will be held in Chicago, September 17-23, with headquarters in the Hotel Stevens. The related organizations will include the American School Health Association and the Conferences of State and Municipal Public Health Engineers, of Public Health Nursing Directors, of Professors of Preventive Medicine, of State and Provincial Public Health Laboratory Directors, of State Directors of Public Health Education and of Industrial Health Consultants. The Illinois committee in charge of local arrangements will be headed by Dr. Herman N. Bundesen, president, Chicago Board of Health, and Dr. Roland R. Cross, state director of public health, Springfield, co-chairmen. The headquarters office of the American Public Health Association is located at 1790 Broadway, New York 19. Dr. Reginald M. Atwater is executive secretary.

Southern Surgical Association—The fifty-sixth annual session of the Southern Surgical Association will be held at the Homestead, Hot Springs, Va., December 5-7, under the presidency of Dr. Alton Ochsner, New Orleans. Among the speakers will be

Dr. Wilham F. Rienhoff, Jr., Baltimore. Analysis of the Results of the Surgical Treatment of Peptic Ulcer of the Duodenum in a Series of 260 Cases

Lieut. Col. James Barrett Brown and Capt. Bradford Cannon, M. C. Repair of Gunshot Wounds of the Face and Jaws

Dr. Louis T. Byars, St. Louis. Color Matching of Skin Grafts and Flaps by Pigment Injection

Lieut. Col. Alfred R. Shands, Jr. and Major Randolph L. Clark, Jr., M. C. Surgical Problems in Aviation Medicine

Lieut. Col. Brian B. Blades, M. C. Penicillin as an Adjunct to the Surgical Treatment of Acute and Chronic Empyemas

Drs. Loyal Davis, George E. Perret and Walter W. Carroll, Chicago. Surgical Principles Underlying the Use of Grafts in the Repair of Peripheral Nerve Injuries

Drs. Thomas B. Aycock and Edward M. Farris, Baltimore. Effects of Sulfonamides on the Mortality Rate in Acute Appendicitis

Drs. Roy D. McClure and Conrad R. Lam, Detroit. End Results in the Treatment of Hyperparathyroidism

Lieut. Col. Lloyd G. Lewis, M. C. Cases of Severe Injury to the Pelvis

Drs. Kenneth L. Pickrell, Durham, N. C. and Richard K. Richards, Chicago. Pentothal Antagonism: A Method of Shortening the Recovery Period Following Pentothal Anesthesia: A Clinical and Experimental Study

Drs. Warfield M. Firor and George O. Gey, Baltimore. Observations on the Conversion of Normal into Malignant Cells

Dr. John M. T. Finney, Jr., Baltimore, and Lieut. Murray L. Johnson (M. C.), Primary Carcinoma of the Gallbladder

Dr. Everett I. Evans, Richmond, Va. Studies on Traumatic Shock

V. The Treatment of Chemical Shock with Gelatin

Drs. Gameel B. Hodge, Keith S. Grimson and Herman M. Schiebel, Durham. Surgical Results of a Revival of Radical One Stage Excision and Stripping of Varicose Veins Coupled with Pressure Bandages and Early Activity

Public Health Cancer Association Formed—The Public Health Cancer Association was recently organized to meet the particular need of persons engaged in cancer control activities in federal, state, city and other official agencies. Active membership is limited to professional workers in such official cancer programs, and officers include Drs. Herbert L. Lombard, Boston, president, Raymond V. Brokaw, Champaign, Ill., vice president, and Morton L. Levin, Albany, N. Y., secretary-treasurer. Included in the membership of the executive committee are Drs. Frank L. Rector, Lansing, Mich., Louis C. Kress, Albany, and Edmund G. Zimmerer, Des Moines, Iowa. Representatives attending the organization meeting felt that the American Association for Cancer Research adequately covered that field that the American Cancer Society is chiefly engaged in lay educational work and that the new organization would meet the particular needs of full time employees engaged in cancer work in the official agencies. It was also felt that such an association would be of value in furthering cancer control by conducting an annual meeting and a cancer symposium in connection with

the annual session of the American Public Health Association. While representatives from about eleven states attended the organization meeting, the membership will not be limited solely to this group.

LATIN AMERICA

Health Activities in Latin America—Physicians Studying in the United States—Among Latin American physicians who are studying in the United States are Drs. Germano Brasiliense Bretz, Brazil, who will go to the Johns Hopkins University, Baltimore, Guillermo Grebe H., tuberculosis specialist connected with the Chilean National Medical Service for Employees, who will do research work in his specialty at Columbia University College of Physicians and Surgeons, New York, Elias Motles, connected with the Sanatorio El Peral of Santiago, Chile, who will study at the Trudeau Sanatorium, Saranac Lake, N. Y., Jose Decusati, Brazil, who will pursue studies in urology at the Massachusetts General Hospital, Boston, Adhemar Paoliello, connected with the Brazilian public health service of Rio de Janeiro, who will study at Johns Hopkins University, Baltimore, and Albino Figueredo, specialist in antepartum hygiene, who will study maternal and child hygiene at the University of Michigan Medical School, Ann Arbor. All of these persons, with the exception of Dr. Paoliello, will first complete a short course in English before continuing with their studies in their specialties.

Mexico's Health—More Mexican patients die from diarrhea and enteritis than from any other disease, it was revealed by the latest mortality figures released by the Mexican Ministry of National Economy. The government statistics, which embrace the years from 1938 to 1942, show that these conditions take an average toll of 90,504 lives annually and that their mortality rate is 45.66 per 10,000. Occupying second place in the ministry's study is pneumonia, which is responsible for an average of 67,560 deaths a year, or a mortality of 34.12 per 10,000. The number of yearly deaths due to other illnesses, and their corresponding mortality rates, are, in the order of their importance, malaria, with an average of 25,454 deaths a year and a mortality rate of 12.9 per 10,000; congenital diseases and those of early childhood, 18,289 and 9.74 per 10,000; whooping cough, 12,893 or 6.5; bronchitis, 12,386 or 6.24; and tuberculosis, 11,066 or 5.6.

Surgical Meeting—The sixth assembly of Mexican surgeons was held at the Juarez Hospital, Mexico City, November 19-25. Speakers and the fields in which they gave papers include Traumatology, Drs. Pablo Mendizabal, Jose Castro Villagrana, Alfonso Ortiz Tirado, Alejandro Castanedo, and Alejandro Malo. Urology, Drs. Eduardo Castro, Adalberto Parra Aquino Villanueva, Manuel Pesqueira, Alberto Madrid, Herbert Stacpoole, and Carlos Aguirre. Neurosurgery, Drs. Clemente Robles, Mariano Vasquez, Alfonso Aceves Zubietta F., Manuel Sanchez Garibay and Miguel Lavalle. Throat and Thorax, Drs. Donato G. Alarcon, Carlos Jimenez Caballero and Julian Gonzalez Mendez. Gynecology, Drs. Conrado Zuckermann, Rosendo Amor, Arturo de los Rios Genaro Zenteno, Fernando Perera Castillo, Gilberto Sousa and Abelardo Monjes Lopez. Obstetrics, Drs. Manuel Mateos Fournier, Jose Rabago Isidro Espinosa y de los Reyes and David Fragos. Pediatrics, Drs. Jesus Lozoya, Guillermo Christy and Vicente Roquemé. Gastroenterology, Drs. Abraham Ayala Gonzalez, Jose Aguilar Alvarez, Gustavo Baz, Jose Gaviola Gandara and Raul Pena Trevino. General Military and Emergency Surgery, Col. Gustavo Gomez Azcarete, Major Rafael Moreno Valle and Drs. Rafael Vargas Otero, Jose Rojo de la Vega, and Alfonso Diaz Infante. There also were sections devoted to ophthalmology and dental surgery.

CORRECTIONS

Dr. Henrik Dam—In the editorial in *THE JOURNAL*, November 4, page 640 concerning the Nobel Prize Awards, it was stated that Dr. Henrik Dam is assistant professor of biochemistry at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y. Dr. Dam is senior research associate at the university, not assistant professor.

Brazilian War Bread—The first four lines of the Brazil letter in *THE JOURNAL*, July 22, page 863 should read "Dr. Castro Barretto, Head Advising Physician of the Technical Department of National Feeding, Ex-Regular Professor of Clinical Medicine of the Faculty of Medicine of Rio de Janeiro and member of the Institute of Brazilian Studies, recently presented a report with the results of his studies on war bread to the Coordinator of Economic Mobilization. The report was approved by the War Bread Commission which was appointed by the Coordinator to study it. The author stresses

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct 22, 1944

Improved Vital Statistics Continue Highest Birth Rate for Nineteen Years

In previous letters the astonishing fact has been reported that our vital statistics have actually improved. The Ministry of Health has just announced the registrar general's returns for the June quarter of 1944 showing that the higher wartime level of the birth rate in England and Wales for which an explanation has been suggested in previous letters was more than maintained. A birth rate of 19.3 per thousand of population is recorded. This is the highest rate of any second quarter since 1925 and compares with a rate of 17.5 in the corresponding period last year and 17.9 for the first three months of this year. There were 199,326 births registered. Of these 102,603 were boys, giving a proportion of 1.061 boys to 1,000 girls. The average proportion of boys to girls for the ten preceding second quarters was 1.056 to 1.000.

For the second quarter in succession a new low record for infant deaths was established. A provisional rate of 4.3 per thousand related live births was 11 below the average of the ten preceding second quarters and was the lowest rate for any June quarter. The general death rate was 11.2 per thousand, compared to 14.2 in the preceding three months and 10.9 for the second quarter of last year. For the same period from 1938 to 1942 the average rate was 12 per thousand. The births exceeded the deaths by 83,801. Corresponding excesses in the second quarters of 1942 and 1943 were 50,674 and 67,802 respectively. Marriages numbered 82,215 and exceeded by 95 those for the corresponding quarter last year. But they were 23,460 fewer than the average for the same period of the years 1938-1942. This falling off is explained by the fact that allowances introduced at the outbreak of war have left comparatively few young people of marriageable age and circumstances unmarried today.

British Prisoners Killed in Allied Air Raids on Germany

In answer to a question in the House of Commons, Mr. Law, minister of state, said that it was unfortunately true that a number of British prisoners of war have lost their lives in allied air raids on the continent, but as the figures could not be given with any accuracy he would not attempt an estimate of them. Under the German prisoner of war system there are main camps to which are attached subsidiary work camps and detachments forming several thousand units scattered all over the country. Some of these camps have been or are situated near legitimate military targets, contrary to article 9 of the Geneva Convention. All available information as to the location of the camps is promptly passed to the Allied air forces and is used in briefing air crews. Whenever the delegates of the protecting power during their periodic visits to camps have observed that our prisoners were dangerously close to a military target they have immediately complained to the German authorities and demanded the transfer of the camp to a safer site. Also the British government made strong representations to the German government through the protecting power. But Mr. Law regretted to say, in several instances the German authorities have not complied with these demands. As an additional precaution the German authorities have been urged to provide adequate air raid protection for our prisoners. There was no evidence to show that casualties in prisoner of war camps said to be due to bombing were in fact executions, he added.

Neglect of Clinical Examination for Laboratory Tests

From time to time feminine teachers issue a warning against the neglect of thorough clinical examination in favor of a multitude of laboratory tests. Thus J. A. Ryke has said that in the past quarter of a century the main endeavor of medicine has been to discover new diagnostic methods. Countless improvements have been due to roentgenology, chemistry and endoscopy, but symptomatology has suffered neglect. Professor Ryke pleaded for a wider and closer clinical study of disease. The current number of the *Army Medical Department Bulletin* presents an article entitled "Clinicians and Special Departments," which points out that in the medicine of today the final and conclusive piece of diagnostic evidence is often supplied by the pathologist or radiologist. But this is bad if it leads physicians to lose their clinical sense, instincts and judgment by turning first to special departments.

The case is quoted from the *Lancet* of a pallid, wasted, elderly man who had suffered from intestinal symptoms for nearly six months. He had a large bundle of documents which included twelve reports on elaborate examinations of his feces and eight on his blood. There was much about the Arnyeth count, as it shifted more or less to the left on occasion. At times the hemoglobin rose 1 or 2 per cent from an average of 65 per cent, an improvement regarded as worthy of congratulation. The sedimentation rate was carefully scrutinized. Though invariably accelerated it exhibited minor variations regarded as of great consequence. The work on the urine comprised every possible sort of investigation. The diagnosis was an atypical infection by an anaerobic streptococcus for which intestinal antiseptics had proved disappointingly inadequate. No examination of the abdomen had been made for at least three months, yet a large tumor was palpable there and exploration exposed a huge cyst of the sigmoid.

Civil Defense Casualties

The German bombing of our cities and towns necessitated the formation of civil defense services to deal with the casualties and damage. At the time of the blitz the members employed amounted to 1,500,000, recently the total was 1,200,000. Members of this service have suffered casualties themselves. Addressing a civil defense parade at Birmingham the home secretary, Mr. Herbert Morrison, stated that some 2,000 members had been killed by the enemy and 8,300 had been seriously injured. There figures did not include casualties to the police and fire services, he added.

Marriages

THOMAS SAMPSON ROYSTER, Henderson, N. C., to Miss Caroline Merck Henry of West Orange, N. J. in Philadelphia September 23.

LESLIE MORGAN MORRIS, Rutherfordton, N. C., to Miss Mary Alice King of Winston-Salem September 9.

CHARLES WALTER METZ JR., Denver to Miss Gloria Evelyn Smith of Nashville, Tenn., September 12.

WILLIAM GORDON LEARY JR., Charlottesville Va. to Miss Margaret Conley of Cincinnati recently.

ROGER ELLISON MACQUIGG, New York to Miss Elizabeth Schill of Newark, N. J. September 30.

CHARLES BENJAMIN HANNA, Enoree, S. C. to Miss Lena Mae Bryant of Nichols, September 19.

JOHN DAWSON HARTIGAN, St. Joseph Mo. to Miss Catherine Leone Fitzpatrick of Omaha recently.

CLARENCE D. LEIPHART, Hellam Pa. to Miss S. Isabelle Mamfold of Bridgeton, October 15.

ROY TURNAGE PARKER, Pinetops, N. C. to Miss Georgie Sugg of Hookerton September 26.

ABRAHAM MELAMED to Miss Hope Goodman both of Milwaukee September 3.

Deaths

Edward Marshall Pallette ☉ a member of the Board of Trustees of the American Medical Association since 1942 died suddenly in Chicago November 15 while in attendance on a session of the Board, apparently of an attack of coronary thrombosis. Dr Pallette was born in Wichita Kan Jan 13 1874. He received the Ph B degree from Northwestern University in 1894 and the Ph M in 1895. During 1894 he did investigation in the field of biology as the Oliver Marcy Scholar of Northwestern University at the Marine Biological Laboratory Woods Hole Mass. He received the degree of doctor of medicine from the College of Medicine of the University of Southern California in 1898 and then did graduate study in the New York Polyclinic in 1901 and in London Vienna and Berlin at various times thereafter. He was assistant instructor of zoology at Northwestern University in 1894 and 1895 instructor in biology in the Los Angeles High School from 1896 to 1898 and at the same time instructor in histology and embryology in the College of Medicine of the University of Southern California. Following his graduation in medicine he began medical practice in Los Angeles giving special attention to gynecology. He was associated with the health department of Los Angeles as assistant health officer from 1898 to 1899 and as a member of the Los Angeles County Board of Health from 1905 to 1906. He taught physiology in the College of Dentistry of the University of Southern California from 1900 to 1912 and was a lecturer in obstetrics and gynecology in the Training School for Nurses of St Vincent's Hospital.

As a distinguished citizen of the state of California he held many special appointments including examiner for the California State Lunacy Commission from 1905 to 1915 membership on the California State Board of Public Health from 1932 to 1940 and member of the Retirement Board of the Los Angeles City Schools from 1938 to 1939. Since 1938 he had served also as treasurer and member of the Board of Directors of the Blue Cross Plan known as the Hospital Service of Southern California.

During World I Dr Pallette served as a captain in the medical corps, serving as surgeon in the Letterman General Hospital at the Presidio in San Francisco and also at Camp Crane in Allentown Pa. In the present war he acted as chairman of the Procurement and Assignment Service for Physicians of the War Manpower Commission in southern California. His interest in general education was exemplified by his membership on the Medical School Advisory Committee of the University of Southern California and the presidency of the Los Angeles County Board of Education.

In the work of the American Medical Association Dr Pallette gave also fully of himself for the advancement of the medical profession. He was a member of the House of Delegates in 1933 1935, 1936 and for the period 1938-1942. He was a member of the California State Medical Association and its president in 1936 1937. He was also a former president of the Los Angeles County Medical Association. His membership in special societies included fellowship in the American College of Surgeons, membership in the Los Angeles Surgical Society, the Los Angeles Obstetrical and Gynecological Society, the Los Angeles Academy of Medicine, the Hollywood Academy of

Medicine, the Institute of American Genealogy and the American Association for the Advancement of Science. Of many of these groups he had been president.

In the death of Dr Pallette the American Medical Association lost a loyal and distinguished counselor, a self-sacrificing and devoted member of its Board of Trustees.

Alexis Carrel ☉ Paris, France died November 5 aged 71. He graduated at the Université de Lyon Faculté de Médecine et de Pharmacie, France, in 1900. He served as prosecutor at his alma mater until 1902, then came to the United States in 1905 and was appointed to the staff of the Rockefeller Institute for Medical Research in New York in 1906. He was made a fellow in 1909 and a member in 1912 and retired in 1939 as member emeritus. In 1912 Dr Carrel was awarded the Nobel Prize in Medicine for success in suturing blood vessels and transplanting organs, this was the first time the prize in medicine had been awarded in the United States. He won the Dr

Sofie Nordhoff-Jung Cancer Prize in 1931 and received the eighth Cardinal Newman Award of the Newman Foundation in 1937. In 1937 he received also the Phi Beta Kappa from Dartmouth College. He was presented with the gold service medal award by the New York Rotary Club in 1939.

During World War I Dr Carrel served as a major in the medical corps of the French army and helped to develop the Carrel-Dakin antiseptic solution for the sterilizing of deep wounds. In 1935 with Colonel Lindbergh, he announced the development of a mechanical heart, in which the heart kidney or glands from an animal could be kept alive for study in glass chambers supplied by circulation of artificial blood. In 1936 he was appointed Hitchcock professor at the University of California in Berkeley for the spring semester.

Dr Carrel was an Associate Fellow of the American Medical Association and a member of the American Society for Experimental Pathology, American Surgical Association, the Society of Clinical Surgery, American Society of Physiology, American Philosophical Society, Accademia Pontificia and the Pontificia Accademia delle Scienze, an honorary fellow of the Royal Society of Medicine, foreign associate Società Italiana delle Scienze and a corresponding member of various foreign academies. Among other

honors he had been decorated Commandeur of the Légion d'honneur, commander of the Order of Leopold of Belgium, member of the Order of the Northern Star of Sweden and commendador de Isabel la Católica. He received the Distinguished Service Medal and was made a companion of the Order of St Michael and St George. He had been a member of the board of the Dazian Foundation for Medical Research New York, since 1937 and was a trustee of the Institute for Advanced Study from 1930 to 1942.

When war broke out Dr Carrel joined a special mission for the French Ministry of Public Health, 1939-1940.

He had received the honorary doctor of science degree from Columbia University, Princeton University, University of the State of New York and Manhattan College, the MD from Belfast and LL D from the University of California. At the time of his death he was director of the Vichy government's Carrel Foundation for the Study of Human Problems. His writing included 'Man the Unknown' and he was joint author with Georges Dehelly of 'Treatment of Infected Wounds' and with Charles A Lindbergh of 'The Culture of Organs'.

EDWARD MARSHALL PALLETTE, 1874-1944

Gardner Weld Allen, Boston Harvard Medical School Boston, 1882, member of the Massachusetts Medical Society, American Association of Genito-Urinary Surgeons, Massachusetts Historical Society, American Antiquarian Society, Naval History Society, American Historical Association, Naval Historical Foundation, Essex Institute, Military Historical Society of Massachusetts and the Lincoln Group of Boston, at one time instructor, assistant professor and professor of genitourinary surgery at the Tufts College Medical School, veteran of the Spanish-American War, surgeon, Massachusetts Naval Militia from 1893 to 1901, formerly surgeon in the genitourinary department of the Boston Dispensary, author of 'Our Navy and the Barbary Corsairs,' 'Our Naval War with France,' 'A Naval History of the American Revolution,' 'Massachusetts Privateers of the Revolution' and 'Our Navy and the West Indian Pirates', editor of 'Papers of Isaac Hull, Commodore U S Navy,' and 'Papers of John Davis Long Secretary of the Navy', contributor of a chapter of Massachusetts in the War of 1812 to 'Commonwealth History of Massachusetts' and eleven naval biographies to the 'Dictionary of American Biography', died July 12, aged 88.

Hugo Erichsen, Birmingham, Mich., University of Vermont College of Medicine, Burlington, 1882, Detroit Medical College, 1882, Royal College of Physicians and Surgeons Kingston Ont., Canada, 1883, professor of neurology at the Quincy College of Medicine, Quincy, Ill., from 1883 to 1885, once city physician of Detroit, past president of the Cremation Association of America, honorary member of the Wayne County Medical Society, member of the Michigan Historical Society and the Michigan Academy of Science, Arts and Letters for many years affiliated with Parke, Davis & Company and the Burroughs Adding Machine Company in Detroit, in 1932 received the honorary degree of doctor of letters from the College of the City of Detroit, decorated by the French government as Chevalier Ordre du Merite Agricole and Officier d'Academie, assistant editor, *Detroit Clinic*, 1883, associate editor *Western Medical Reporter* 1883-1884, editor of the photographic department, *American Boy*, from 1903 to 1913, author of 'Medical Rhymes,' 'Cremation of the Dead,' 'Methods of Autopsies' and 'Roses and Ashes', died in the Harper Hospital, Detroit, October 10, aged 84.

Frank Hilton McLeod, Florence, S. C., University of Tennessee College of Medicine, Memphis, 1888, member of the Southeastern Surgical Congress, past president of the South Carolina Medical Association, Florence County Medical Society and the Tri-State Medical Society, counselor of the Southern Medical Association from 1929 to 1935, fellow of the American College of Surgeons, in 1906 established the Florence Infirmary, now known as the McLeod Infirmary of which he had been medical superintendent and surgeon in chief, for many years regent at the South Carolina State Hospital, Columbia, awarded the distinguished service plaque for 1941 by the South Carolina department of the American Legion, in 1943 a bronze bust of him was presented to the McLeod Infirmary to mark his many years service to the community, in 1928 received the Sullivan Award of the University of South Carolina, in 1935 received the honorary doctor of laws from the University of South Carolina, at one time editor of the *Journal of the South Carolina Medical Association*, died October 24, aged 76.

Jerome Joseph McCaffrey, Providence, R. I., Harvard Medical School Boston, 1915, member of the New England Society of Psychiatry, a charter member and past president of the Rhode Island Society for Neurology and Psychiatry, served in France during World War I, a first lieutenant in the medical corps of the U. S. Army and adjutant and personnel officer of Evacuation Hospital number 34, American Expeditionary Forces, formerly chief of the State Division of Hospitals and Infirmaries, since 1930 on the neuropsychiatric staff of the Charles V. Chapin Hospital, consultant neurologist at the State Infirmary, Howard, on the neurologic staffs of St. Joseph's Hospital and the Rhode Island Hospital where he died October 16, aged 56.

Ward Denver Coffman, Zanesville, Ohio, University of Cincinnati College of Medicine, 1919, fellow of the American College of Surgeons, past president of the Muskingum County Academy of Medicine, appointed a member in 1939 and in 1943 chairman of the Ohio Public Health Council, president of the board of education of Zanesville for a second term, served in the medical corps of the U. S. Army during World War I, formerly chief of the staffs of the Bethesda and Good Samaritan hospitals, at one time public school physician at Springfield, died in the Lake of the Woods, Nestor Falls, Ont., Canada, September 7, aged 53, of myocarditis.

Douglas C. Moriarta, Saratoga Springs, N. Y., Albany Medical College, Albany, 1885, also a pharmacist, member

of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, fellow of the American College of Surgeons, formerly city physician, health officer and county coroner, past president of the chamber of commerce, medical examiner for the draft board during World War I, served as chief surgeon at St. Christina's Hospital for fifty years, a member of the staff of the Saratoga Hospital where he died September 12, aged 85, of hypostatic pneumonia and diabetes mellitus.

Arthur Grant Jacobs, Memphis, Tenn., University of Virginia Department of Medicine, Charlottesville, 1896, Medical College of Ohio, Cincinnati, 1897, professor of pediatrics at the University of Tennessee College of Medicine, specialist certified by the American Board of Pediatrics, Inc., member of the American Academy of Pediatrics, chief, department of pediatrics, Baptist Memorial Hospital and the John Gaston Hospital, visiting pediatrician to the Crippled Children's Hospital School, died in the Methodist Hospital, November 3, aged 69.

Stillwell Corson Burns, Philadelphia, Medical-Chirurgical College of Philadelphia, 1898, fellow of the American College of Surgeons, formerly associate professor of surgery at the Medical-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, a major in the U. S. Army during World War I, served as surgeon in the Graduate Hospital of the University of Pennsylvania for twenty-five years, chief surgeon for the Baldwin Locomotive Works, died November 1, aged 69, of carcinoma.

Hiram Rand Corson, Issaquah, Wash., Medical School of Maine, Portland, 1876, formerly physician to the State Soldiers Home in Orting, died September 18, aged 95, of arteriosclerosis and mesenteric thrombosis.

Leon Charles Cote, Newburgh, N. Y., Albany Medical College, Albany, N. Y., 1917, a captain in the medical corps of the U. S. Army, serving overseas during World War I, served as president of the Newburgh Bay Medical Society, on the courtesy staff of the Highland Hospital, Beacon, on the staffs of the Wallkill State Prison Hospital, Wallkill, Cornwall Hospital, Cornwall and the Municipal Sanatorium, Otisville, died September 27, aged 57.

Edward McClelland Cowell, Athens, Pa., Chicago Homeopathic Medical College, 1885, a captain in the medical corps of the U. S. Army during World War I, served on the staff of the Tioga County General Hospital, Waverly, N. Y., died in Waverly, N. Y., September 1, aged 80, of coronary occlusion.

Orlando Aaron Rogers Donnelly, Chicago, Bennett Medical College, Chicago, 1913, served as a captain in the medical corps of the U. S. Army during World War I, for many years connected with the city health department, died in the Veterans Administration Facility, Hines, September 6, aged 65, of carcinoma of the sigmoid colon.

Edwin William Dyar, Ossian, Ind., Medical College of Indiana, Indianapolis, 1904, member of the Indiana State Medical Association, vice president and formerly president of the Ossian Bank, for many years on the staff of the Lutheran Hospital, Fort Wayne, died September 11, aged 64, of hypostatic pneumonia.

John Adair Elliott, Chicago, Jenner Medical College, Chicago, 1908, died in St. Francis Hospital, Evanston, Ill., September 26, aged 66, of bronchial asthma and myocardial insufficiency.

Evan Alexander Erwin, Laurinburg, N. C., Medical College of the State of South Carolina, Charleston, 1912, member of the Medical Society of the State of North Carolina, secretary of the Scotland County Medical Society, served as county health officer, died September 20, aged 59, of carcinoma.

Herbert Kimball Faulkner, Keene, N. H., Harvard Medical School, Boston, 1885, member of the New Hampshire Medical Society, formerly surgeon and trustee to the Elliot Community Hospital, served as trustee to the Keene Public Library, had been director of Faulkner and Colony Mills, the Cheshire National Bank and the New Hampshire Fire Insurance Company, died September 15, aged 85, of arteriosclerosis.

D. Harold Finch, Laramie, Wyo., Jefferson Medical College of Philadelphia, 1917, died in Provo, Utah, September 4, aged 55, of hypertension and arteriosclerosis.

Eliezer Israel Fogel, Cincinnati, Ohio-Miami Medical College of the University of Cincinnati, 1909, served during World War I on the staff of the Jewish Hospital where he died September 11, aged 57, of coronary occlusion.

James Lyle Fortune, Terre Haute, Ind., Medical College of Indiana, Indianapolis, 1903, formerly county coroner, examining physician for the Redstone Arsenal in Huntsville, Ala.

examining physician for the Shriners' Hospital for Crippled Children, St Louis, died in St Anthony's Hospital September 26, aged 64, of cerebral hemorrhage

Arthur Edmund Gilster * Chicago, the Hahnemann Medical College and Hospital, Chicago, 1910, on the staff of the Swedish Covenant Hospital, where he died September 14 aged 57, of coronary thrombosis

Harry E Grishaw, Tipton, Ind Central College of Physicians and Surgeons, Indianapolis, 1897, member of the Indiana State Medical Association, health officer of Tipton County, on the staff of the Mercy Hospital, Elwood died September 28, aged 71, of chronic nephritis and cardiac insufficiency

John Edge Maines * Lake Butler, Fla, Atlanta College of Physicians and Surgeons, 1905 died August 21, aged 68, of coronary occlusion

William Jackson Mason, Lawton, Okla Beaumont Hospital Medical College, St Louis, 1894, on the staff of the Angus Hospital where he died July 13, aged 78, of carcinoma of the liver

Robert Keating McConeghy, Coudersport, Pa, Jefferson Medical College of Philadelphia, 1908, past president of the Potter County Medical Society served as coroner of Potter County for one term on the staff of the Coudersport General Hospital, died in the Pennsylvania State Tuberculosis Sanatorium number 2, Cresson, July 27, aged 60 of pulmonary tuberculosis

Morris Spencer McGuire, Boonville, Mo., Missouri Medical College, St Louis, 1895 University of Missouri School of Medicine Columbia, 1895 on the staff of St Joseph's Hospital, where he died August 31 aged 69, of myocarditis and angina pectoris

William Thomas Meeks, Blairsville, Ga, Atlanta Medical College, 1915 died July 10, aged 69, of coronary thrombosis

Andrew Gazik Opinsky, New Kensington Pa, Medical College of Virginia, Richmond 1910, member of the Medical Society of the State of Pennsylvania, contract surgeon for the U S Army, served as camp surgeon for the Civilian Conservation Corps camps died July 30, aged 63, of coronary thrombosis

James Willis Parker, Grand Blanc, Mich University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898 a member of the board of education for many years, on the staff of the Goodrich General Hospital, Goodrich, died in Cadillac August 24, aged 72 of coronary occlusion

Charles Hurd Ross, Alliance Ohio, Columbus Medical College 1892 member of the staff of the Alliance City Hospital died August 11 aged 76 of plasma cell myeloma

Peter Maurice Ross, Lake Beulah, Wis Milwaukee Medical College, Milwaukee, 1898, served on the staffs of St Joseph's and St Mary's hospitals in Milwaukee died August 24, aged 72 of coronary occlusion

Florian A Ruest, Pawtucket R I, School of Medicine and Surgery, Faculty of Medicine of the University of Laval at Montreal, Que Canada, 1896 member of the New England Obstetrical and Gynecological Society and the Rhode Island Medical Society, for many years health officer of Pawtucket formerly on the staff of the Park Place Hospital, medical adviser of l'Union St Jean Baptiste d'Amerique since 1911, died in the Memorial Hospital August 2, aged 75, of uraemia

Frank Lyon Salisbury * Russellville, Ohio, Ohio State University College of Medicine, Columbus, 1917 served as a first lieutenant in the medical corps of the U S Army during World War I died August 1, aged 51, of coronary thrombosis

Howard Frederick Schultz, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1905, on the courtesy staff of the Abington Memorial Hospital, Abington and the Hahnemann Hospital, died August 27 aged 61 of coronary thrombosis

Claude Howard Searle, Chicago, Rush Medical College Chicago, 1898, chairman of the board of directors since 1936 and president from 1917 to 1936 of G D Searle & Company, major in the medical corps of the Illinois National Guard

during World War I, a founder and formerly secretary and president of the American Pharmaceutical Manufacturers Association, serving also as a member of the executive committee, died in the Evanston Hospital, Evanston, Ill, October 22 aged 71, of pneumonia

Charles Porter Shaffer, La Verne, Calif, St Louis College of Physicians and Surgeons, 1892, Jefferson Medical College of Philadelphia, 1895 died August 10, aged 81, of carcinoma

Samuel Sher, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1907, member of the Illinois State Medical Society, served as professor of diseases of the ear, nose and throat Post-Graduate Medical School, formerly on the staff of the Cook County Hospital, on the staffs of Grant and Edgewater hospitals and on the courtesy staff of the Wesley Memorial Hospital, where he died October 25, aged 59, of cerebral hemorrhage and arterial hypertension

Simon Small, Boston, Tufts College Medical School, Boston, 1930, died in Lexington, Mass, July 29, aged 39

Frederick Adams Smith * Troy, N Y, College of Physicians and Surgeons, New York, 1891, served on the staffs of the Samaritan and the Leonard hospitals died August 7 aged 76, of carcinoma of the adrenal gland

Charles Ivar Spannare, Los Angeles, Bennett Medical College, Chicago, 1910, died in the Los Angeles County Hospital July 1, aged 62, of myocardial infarction and acute left ventricular failure

William Harrold Spinks, Washington, D C, Washington Homeopathic Medical College, 1894 died in the Galinger Hospital August 19, aged 68 of malignant hypernephroma of the right kidney

Claud Milton Stewart, Lufkin, Texas Meharry Medical College, Nashville, Tenn, 1928, died July 18, aged 46

George W Stratton * Marysville, Calif, Missouri Medical College St Louis, 1888, died August 29, aged 79

Francis Hall Sullivan, Miami, Mo Marion-Sims College of Medicine, St Louis, 1898, member of the Missouri State Medical Association, died August 14, aged 72 of cerebral hemorrhage

James Henry Talboy, Boquette, Republic of Panama, State University of Iowa College of Medicine, Iowa City, 1884 died August 12, aged 82, of encephalomalacia

Ralph Tousey, Seattle, Columbia University College of Physicians and Surgeons New York, 1898, died September 25, aged 70

Alexander Loudin Turner, Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912 member of the Michigan State Medical Society, served on the staffs of the Grace and Woman's hospitals died in Ravenna Ohio August 12, aged 61, of coronary thrombosis

John Samuel Whitson, Enderlin, N D, Rush Medical College Chicago, 1895, died August 6, aged 76 of arterio sclerosis

Ossie Frank Wilmeth, Oakland Calif Lincoln Medical College, Eclectic, Lincoln, Neb, 1916, member of the California Medical Association died in the Providence Hospital August 26, aged 54, of coronary thrombosis

Fredericka Caroline Zeller, Peoria, Ill, Northwestern University Woman's Medical School, Chicago, 1894, died in the Methodist Hospital August 28, aged 80, of perforated appendicitis

KILLED IN ACTION

Lester Cecil O Neal * Andalusia, Ala Louisiana State University School of Medicine, New Orleans 1934 commissioned a captain in the U S Army (National Guard) on June 29 1940, began active duty as a major on Nov 25, 1940 killed in action in Italy Nov 7 1943 aged 36

MAJOR LESTER C O NEAL, U S A
(National Guard) 1906-1943

DISAGREEMENT ON SILICOSIS DUE TO WHEAT DUST

To the Editor—"A Case of Silicosis Caused by Wheat Dust" by Heatley, Kahn and Rex of Toledo, Ohio, published in THE JOURNAL, April 1 is without scientific merit and should not have been accepted for publication.

A claim for silicosis compensation has been presented to the Ohio Industrial Commission on behalf of the patient whose condition is described in the article mentioned. The commissioners who are not physicians, cannot help being impressed by the fact that a medical journal has accepted for publication an article which purports to prove that silicosis can be caused by exposure to wheat dust.

I submit some of the more obvious and significant points on which I believe the article is subject to criticism.

1 The occupational history is incomplete and does not exclude the possibility of silica exposures other than the one which is alleged by the authors.

2 The first of two x-ray films of the chest is reported to show mottling in the left lung but there is no mention of mottling or any other type of shadow indicating parenchymatous change in the right lung. In the description of the second x-ray film, made two years later, there is no mention of any type of mottling or nodulation in either lung nor do the published reproductions of these films show any. The only obvious findings described are in the hilar shadows and linear markings. Authorities are agreed that a diagnosis of silicosis cannot be based on exaggerated linear markings and increased hilar shadows alone, yet the authors report "a roentgenogram typical of advanced silicosis."

3 The authors give no dust counts. They state that 20 per cent of the dust analyzed was between 1 and 44 microns in particle size. They do not state how much of it was below 10 microns, which is recognized as the upper limit of size of silica particles which are capable of producing disease.

4 The dust which the authors analyzed is said to have come from a railroad car and a tunnel, but they do not state whether it came from the atmosphere breathed by the workmen or was scraped up from the floors.

5 A chemical analysis is submitted showing that this dust contained certain percentages of "silica." Chemical analysis does not distinguish between free silica and silicates. No petrographic examination or x-ray diffraction examination is reported. The authors, therefore have not proved the presence of silicon dioxide in the dust analyzed.

6 The authors report that the second examination of the patient, after a two year interval showed diminished vital capacity and increased emphysema, which is inferred to be the immediate cause of the patient's disability. They give no vital capacity measurements and do not mention any of the clinical or x-ray data on which their diagnosis of emphysema is based. It is the opinion of Gardner and other authorities that emphysema does not develop as a complication of silicosis until the silicosis has reached an advanced stage with extensive conglomeration of the nodular shadows.

7 The authors state that a comparison of the two x-ray films showed that the heart shadow contour had changed as a result of the changed lung condition. They do not describe the nature of this change nor do the reproductions of the x-ray films show it. The only type of heart disease which might be induced either by emphysema or by advanced silicosis is cor

pulmonale. This is a difficult clinical diagnosis to make and probably no experienced cardiologist would attempt to make it without the help of an electrocardiogram. No electrocardiogram was reported in this case.

In conclusion it is my contention that the authors have submitted no proof that their patient either had silicosis or had been exposed to silicon dioxide present in wheat dust.

NOMENCLATURE OF PAPPATACI OR PAPATACI FEVER

To the Editor—May I make a few observations regarding the paper of Sabin Philip and Paul in THE JOURNAL July 1 concerning the nomenclature of Papataci fever. As the authors in footnote 2 on page 603 state the name of the vector is *Phlebotomus papatasi* Scolopi. Papa = he cats, tas = silently, a derivative from the Italian (see also Galli Valerio C. Bact. 063:226).

As can readily be seen there is no justification for using a double p. The disease was written with a double p by the first describer (Doerr), but he stated that he used the double p for 'reasons of priority' an illogical point of view because the etymologic derivation and the name of the vector undoubtedly speak in favor of one p.

Perhaps some readers will be interested in two other synonyms of the disease. They are soldier's fever (because the invading Austrian troops in Bosnia were stricken but not the native population) and 'dog's disease' used in Dalmatia.

MEDICOLEGAL ABSTRACTS

Narcotics Validity of Opium Poppy Control Act as Applied to Grower of Poppy Seed for Food Purposes— The Federal Opium Poppy Control Act of 1942 (56 Stat. 1045, 21 U. S. C. A., sec. 188 et seq.) prohibits and imposes a penalty for the production of opium poppies except when done by virtue of a license issued by the Secretary of the Treasury and defines the term 'opium poppy' to include the plant *Papaver somniferum* and any part of any such plant. Certain growers in California of the blue seeded poppy or the species known botanically as *Papaver somniferum* who cultivated these poppies for their seed, an edible food product, apparently were unable to obtain a license to produce the poppy species in question for food purposes. They then brought suit in the district court, N. D. California, N. D., to enjoin the Bureau of Narcotics of the Department of the Treasury of the United States and the United States government officials charged with the enforcement of the act from interfering in any way with the growing and production of their crop of poppies. Admittedly, while the seeds of this species of poppy can be used as an edible food product, other parts of the plant are a source of opium and opium derivatives including morphine the fluid obtained through incisions cut in the pod yielding what is called the raw opium. Nevertheless the growers contended that the

Opium Poppy Control Act as applied to them is unconstitutional because it is an exercise by the United States of regulatory powers over the production of an agricultural commodity, the poppy seed within a state and that such powers are reserved exclusively to the states by the Tenth Amendment to the Constitution.

The Opium Poppy Control Act said the district court does not purport to regulate the production of an agricultural crop. The act is directed to the growth of opium yielding poppy plants within the United States as the source not of an edible food product but rather of raw opium. Its effect on the production of the poppy seed is incidental only to its operation on a plant that produces both a narcotic drug and an edible seed. The validity of the act does not depend on a finding of constitutional authority in the federal Congress to regulate a food supply but on the power of Congress to regulate the supply source of raw opium. The primary derivation of congressional authority to exercise control by federal legislation over the cultivation of the opium poppy is stated in the declared purpose of the act here in question:

(1) to discharge more effectively the obligations of the United States under the International Opium Convention of 1912 and the Convention for Limiting the Manufacture and Regulating the Distribution of Narcotic Drugs of 1931.

The prime objective of the International Opium Convention of 1912 was to eradicate the opium evil and one of the methods therein agreed to to accomplish that end was through the exercise of control over the production and distribution of raw opium, defined in chapter I of the convention as

the spontaneously coagulated sap obtained from capsules of the opiorhizis poppy (*Papaver somniferum*) and which shall not have been subjected to any but the processes necessary to the picking and the transportation thereof.

The later Convention for Limiting the Manufacture and Regulating the Distribution of Narcotic Drugs of 1931 (Treaty Series No. 863, 48 Stat. 1543) to which the United States was signatory was in furtherance of the same objective as the International Opium Convention of 1912—the eradication of the drug evil by rendering effective by international agreement the limitation of the manufacture of narcotic drugs to the world's legitimate requirements for medical and scientific purposes and by regulating their distribution.

The competence of the United States continued the court to enter into treaty stipulations with foreign powers designed to establish through appropriate legislation an internationally effective system of control over the production and distribution of habit forming drugs cannot be questioned, since the obligations the government there incurred were lawfully undertaken in the proper exercise of its treaty making power. And Congress is constitutionally empowered to enact whatever legislation is necessary and proper for carrying into execution the treaty making power of the United States. *Velev v. Henkel*, 180 U. S. 109, 21 S. Ct. 302, 45 L. Ed. 448. By the terms of the International Opium Convention of 1912 the United States obligated itself to control the production and distribution of raw opium. The provisions of the Opium Poppy Control Act express the determination of Congress that effective control of opium production and distribution necessitates legislation limiting the proximate source of yield of the raw opium—the opium poppy—whatever the purpose for which its cultivation is undertaken.

The constitutionality of the measures thus chosen by Congress to give effect to the treaty stipulations of the convention is not dependent on the wisdom or success of the choice. Nor is it significant that the two conventions contain no stipulation expressly committing the signatory powers to the obligation of exercising control over the cultivation of the opium poppy. The power of Congress to enact such legislation as is

necessary or proper to carry into execution powers vested by the Constitution in the United States, of which the treaty making power is one, includes the right to employ any legislative measures appropriately adapted to the effective exercise of those powers. So long as a rationally sound basis exists for the congressional determination that particular legislation is appropriately related to the discharge of constitutional powers, the validity of such legislation is unassailable.

It was apparent to the court that efficacious control over the production and distribution of raw opium can well depend on the limitation of the cultivation of the opium poppy within the United States to legitimate medical and scientific needs only. The appropriate relationship, said the court, of the means adopted by Congress to the ends thereby sought to be attained is evident. The opium poppy is the immediate source from which the raw opium is obtained, its cultivation may be undertaken without difficulty, without detection and for illicit purposes even under the guise of legitimate pretenses, the process of extracting the raw opium from the opium poppy is a simple one, the growth of the opium poppy, wherever undertaken, can reasonably be said to afford attractiveness to those seeking a source of opium supply either for the satisfaction of their own cravings or for the profits offered by the contraband market, and this attractiveness can be expected to increase as suppression of the drug evil becomes progressively more effective and other sources of drug supply become more scarce. In view of these considerations alone, this court is satisfied with the appropriate relativity of measures limiting the cultivation of the opium poppy to the objectives of the treaty stipulation to control the production and distribution of raw opium.

The court accordingly held that the Opium Control Act of 1942 was constitutional and denied injunctions to restrain enforcement of the Act—*Stutz v. Bureau of Narcotics of Department of Treasury of United States*, *Schlain v. Sami*, 36-1 Supp. 810 (Calif., 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1954 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Vaginal Delivery Following Cesarean Section—Kuder and Dotter point out that there is a difference of opinion concerning the nature of the first vaginal delivery occurring in a patient who has had a cesarean section. The question is whether or not the labor is comparable to that of a multipara or a primipara, especially in regard to the total duration of labor and the course of the first stage of labor. This study comprises a review of 34356 pregnancies occurring in the Woman's Clinic of the New York Hospital. Of this total 496 patients had a previous cesarean section. In this group 109 patients were delivered of a full term or premature infant vaginally without ever having had a vaginal delivery preceding the first cesarean section. It was found that the average duration of labor of the first vaginal delivery in a patient who was delivered by cesarean section in her first pregnancy is identical with that in a primipara.

Postpartum Salpingitis and One Child Sterility—Black-Schaffer presents pathologic studies consisting of bilateral tubal segments removed in the course of sterilization from 67 patients. Of this number 50 were obtained post partum following normal delivery and the remaining 17, used as controls, from patients who had undergone cesarean section. The chief indications for sterilization were, in the order of their frequency, multiparity, severe toxemias of pregnancy and heart disease. All the patients with 1 exception, were operated on at some time between the second and the twelfth postpartum day. Bilateral tubal segments were examined microscopically. The 17 cesarean section pairs (controls) showed no pathologic lesions. Of the 50 postpartum pairs 19 were the site of a mild acute salpingitis. In no case was the salpingitis clinically recognized. It is suggested that this hitherto not demonstrated but suspected puerperal salpingitis may in some patients be the cause of tubal obstruction with resultant reduction of fertility or even sterility.

Chorea Gravidarum—Ruch presents the history of a woman aged 20 in whom symptoms of chorea began during the second month of pregnancy. Despite rest in bed, a high vitamin diet and sedation the symptoms continued and gradually increased

until during the sixth month of pregnancy, they suddenly became quite severe. Cesarean section was performed. The contractions had practically disappeared by the time she left the hospital two weeks after operation. The appearance of the symptoms during the first trimester of pregnancy and the lack of organic disturbances seemed to rule out toxemia as the etiologic factor. The author thinks that fatigue was a strong influence and that either the attack of measles or an unsuspected mild rheumatic fever in childhood was primarily responsible.

The early onset, the intermittent low grade fever and the attack of acute arthritis after recovery from the operation support this view.

Heterogenous Skin Grafts by Coagulum Contact Method—Harris reports that a girl aged 12, one side of whose body including the entire upper and lower extremity had been burned completely, was in an extremely poor condition after four months of ineffective treatment. Since she had no skin to spare a graft was taken from her father. The results of the grafting were excellent; the take was perfect. The only objectionable feature was the fact that blood had to be taken from the patient and thus she resented because of the pain so that the author was hesitant to take even 20 cc of blood for another graft. At a second graft it was decided to use the plasma and cell extract as well as the skin from the father. The procedure was done and two drums full of skin, the same size as the first one (10 by 15 cm) were taken and applied to the pelvis and buttock. These grafts also showed a complete take. Since the father could not donate any more skin it was decided to try a heterogenous isograft with a stock blood plasma and cell extract. The results of this also were excellent. The author reports 8 other cases. Sano removes the graft and places it on a piece of gauze and then paints on the cell extract. The author paints the cell extract on the graft while it is still on the drum when the Padgett machines are used. Painting the cell extract on the graft while still on the drum might be advantageous because the fluid has a better opportunity to fill all the interstices. After it is removed from the drum the graft shrinks but the entire surface of the graft will have been covered, with the result that it has a better chance of agglutinating to the entire surface. Complete hemostasis must be accomplished in all cases before the grafts are applied.

Tyrothricin in Ulcers of Skin—Rankin describes 6 cases of old chronic ulcers in which tyrothricin was used. Tyrothricin consists of gramicidin and tyrocidine. Reports show that it is of value in the treatment of mastoiditis, empyema, suppuration, arthritis and deep wound infections. While investigators mention the action of tyrothricin on the bacteria in the ulcer no mention has been made of one property that the author noticed in 5 of the 6 patients treated, namely, tissue stimulation. Tyrothricin did not cause toxic symptoms in the 6 patients; it was a

good antibactericidal agent when applied locally it caused no pain or discomfort when used locally in the proportion of 0.25 cc to 99.75 cc of water. Excellent results were obtained in 5 of the 6 patients.

Some Clinical Characteristics of Mumps and Effect of Belladonna in Treatment Study Made at Station Hospital Fort George G Meade Maryland H W Potter and L H Bronstein—p 469

Impending Myocardial Infarction—According to Waitzkin acute myocardial infarction is preceded by premonitory symptoms in a considerable percentage of cases. He found that of 61 consecutive cases of acute infarction treated in the past two years 17 showed premonitory symptoms. The symptoms have the following characteristics: 1 There may be one or more episodes of spontaneous prolonged cardiac pain mild or severe with or without a preceding history of coronary artery disease. 2 Cardiac pain of short duration, on customary or no exertion suddenly appears where none existed before. 3 In patients with preexisting angina pectoris cardiac pain appears on rapidly decreasing amounts of exertion or at rest. In considering symptoms suspected as premonitory it must be recognized that myocardial infarction does not inevitably follow them but the strong possibility that it may should lead to suspicion and therapeutic precautions.

Clinical Characteristics of Mumps, and Effect of Belladonna in Treatment—Potter and Bronstein review 124 cases of mumps. This study was originally undertaken in an effort to ascertain the value of treating such patients with belladonna. The use of this drug had been suggested to shorten the course of the disease and to decrease the incidence of complications.

On admission the soldier was given $\frac{1}{400}$ grain (0.65 mg) of atropine sulfate and then 1 cc of the tincture of belladonna by mouth every two hours, until atropinization, as evidenced by dilatation of the pupil and/or dryness of the throat, was produced. Subsequent medication was given in doses to keep these changes constant either until the patient was cured or until gastrointestinal discomfort made it necessary to discontinue the drug. Belladonna was used in treating 42 of these cases without any effect on the duration of illness, incidence of complications, duration of orchitis or comfort of the patient. The distinction between rural and urban origin of the soldier is no longer as definite as it was in previously reported series of cases, probably because of decreased isolation of population groups. Most of the men developed mumps within their first year of service and possible exposure and not in the first two months as reported in the first world war. Early hospitalization does not shorten the duration of the disease.

*Early Syphilis Masked and Delayed by Penicillin in Treatment of Gonorrhea Bertha Shafer and S J Zakon—p 200

Dermatophytosis in Industry—Peck and his associates examined for dermatophytosis 2,123 workers in two munitions plants, three plants processing steel and other metal parts and one plant making glass products. Two of the plants were revisited at different seasons. On clinical grounds alone results for the 2,123 workers were classified as 27.79 per cent positive, 33.63 per cent doubtful and 38.57 per cent negative. Cultural studies revealed that some patients in the clinically doubtful group had true dermatophytosis. There was no significant difference in sex incidence. When the personnel of the same plants was examined at different seasons the number of clinically negative workers rose from 13 to 19 per cent in the summer to 54 per cent in the winter. *Trichophyton gypsum* was the pathogenic fungus most often recovered, *Trichophyton purpureum* was next in frequency and *Trichophyton mignone* was recovered from 1 case. All of the cultures of *T. purpureum* were recovered in one locality. Shower room flooring of concrete or pine wood is a possible but not likely source of fungous infections of the feet. Copper impregnated concrete flooring was found to be of no value in the prevention of the spread of fungous infections of the feet. *Trichophyton* tests were made on 776 workers. Of these 42.53 per cent had positive reactions. Of the 558 men tested, 52 per cent had positive trichophyton tests. Of 216 women tested 29.96 per cent had positive trichophyton tests. Lower incidence in women of a demonstrable allergy to fungi and/or their products may explain why women are less affected by dermatophytosis of the feet than are men since it may be responsible for less subjective symptoms. The trichophyton test is more often positive in patients with clinically active dermatophytosis of the feet than in those showing no evidence of the disease. There is no indication that the presence of an allergy to fungi and/or their products bears any relationship to the acquisition of an allergic contact dermatitis. Dermatophytosis and its allergic manifestations are not important factors in lost time among industrial workers.

Dyskeratosis Congenita, Dystrophia Unguium and Leukoplakia Oris—Garb and Rubin report the histories of 2 brothers with dyskeratosis congenita with pigmentation, dystrophia unguium and leukoplakia oris, a rare dermatosis. This syndrome has been described by Cole, Rauschkolb and Toomey who reported 1 case and discussed 2 which had been observed by Engman. All 5 cases have in common pigmentation, leukoplakia oris and dystrophy of the finger nails and toe nails. They also have a change in the skin of the hands resembling acroder-

matitis chronica atrophicans The cases seen by the authors differed from those of Cole, Rauschkolb and Toomey and Engman in the character of pigmentation, which consisted of rhomboid-like purplish spaces enclosing normal skin, in contrast to the whitish raised papules with a fine reddish base in the patient of Cole and his associates and to the 1 mm spots surrounded by pigment arrayed in a peculiar network in Engman's case. The lesions of the mouth and the nails were similar to those of the other 3 cases except that the leukoplakic lesions in the older brother were more extensive and were complicated by bullae and ulcerations of the commissures of the lips. His nails were more dystrophic than those of his younger brother and the other 3 patients. The brothers had additional features, the most important being mental retardation. There was evidence of vitamin B complex deficiency in all 5 cases so far reported. This was manifested chiefly by leukoplakia, dystrophy of the nails and in the first of the reported cases by intestinal hypomotility. This patient was treated at first with testosterone propionate, to which the leukoplakic patches responded well, undergoing pronounced regression in three weeks, and recently with large doses of vitamin B complex.

Early Syphilis Masked by Penicillin Used for Gonorrhea—Shafer and Zakon point out that penicillin is the first therapeutic agent to be effective in the treatment of both gonorrhea and syphilis. However, the difference in the apparently curative doses of penicillin in the treatment of these two diseases presents a grave problem in that early syphilis may be masked and delayed by the use of doses of penicillin which are curative for gonorrhea but which are totally inadequate for syphilis. This problem is illustrated with a case report.

Archives of Surgery, Chicago

*Aseptic Necrosis of Head of Femur Following Traumatic Dislocation of Hip S Kleinberg—p 104
Review of Urologic Surgery A J Scholl and others—p 109

Plasma Cell Mastitis—Plasma cell mastitis of Adair is a relatively uncommon disease. It is important because of its clinical resemblance to carcinoma of the breast. The resemblance is so close that in at least half of the recorded cases primary radical mastectomy was performed on the assumption that the condition was malignant. The 5 specimens reported in this communication were collected by Parsons and his collaborators from a total of 1,500 specimens from female breasts studied during the past six and a half years from the services of the Vicksburg Hospital and from other sources in Mississippi. The clinical features of these cases duplicate those common to most of the other recorded cases. In case 1 the resemblance to carcinoma of the breast was embarrassingly close. In case 2 the lesion was more suggestive of an inflammatory process, although it was only moderately tender, and the nipple was retracted. Some features of this disease have not been reported before, including recurrence of the lesion, which was observed in cases 2 and 3, and diffuse comedomastitis, which coexisted in portions of the mammary glands in cases 1 and 5. In case 2 the tonsils were badly diseased and the speculation is advanced that the focal infection may have contributed to the development of the mastitis, because in another case of indolent mastitis trouble with the breast continued until tonsillectomy was carried out, after which, without other therapy, the mastitis promptly subsided. The first patient went through a normal pregnancy in the same year in which her breast was removed without the development of mastitis in the remaining breast. The second patient had been castrated five years before the onset of symptoms referable to the breast and the course of the plasma cell mastitis covered three years, which is an unusually prolonged time for this condition. The apparent difference in the endocrine constitution in the 2 cases seems worthy of comment. The condition is a periductal inflammatory reaction caused by extravasation of material from the ducts into the periductal fibrous tissue and is a true clinical entity.

Aseptic Necrosis of Head of Femur—Kleinberg calls attention to the possibility of traumatic dislocation of the hip occurring without rupture of the ligamentum teres. He reports a typical case of aseptic necrosis and deformity of the head of the femur with its ligamentum teres intact and thoroughly vascularized, the pathologic condition having arisen from a traumatic interruption of the blood supply of the femoral head coming through the capsule of the hip joint. From experience in operations on the hip joint in which the femoral head is deliberately dislocated from the acetabulum the author has learned that, whereas most of the time the ligament is torn if manipulations have not been sudden or violent the head can be pried out of the acetabulum without rupturing the ligament. It is possible, therefore, to visualize a traumatic dislocation of the hip without rupture of the ligamentum teres. That must have been true in the case here reported. The force producing the dislocation tore the capsule and its blood vessels, thereby depriving the femoral head of a large source of its blood supply. As a result there ensued an aseptic necrosis with collapse of the bony structure arising from too early weight bearing. One might assume that the ligamentum teres had been torn but that the fragments had fortuitously come accurately and intimately in contact after the reduction and had reunited. But in such an event, which is extremely unlikely there would remain some scars of healing, and none were visible. The normal ligamentum teres in the reported case proves that rupture of the ligament is not a constant occurrence in a traumatic dislocation and that typical aseptic necrosis of the femoral head may occur even though its blood supply through the ligamentum teres has not been disturbed.

Sulfonamides in Chronic Bronchial Infections—The report is concerned with the use of sulfadiazine, sulfamerazine and sulfathiazole in 48 cases with purulent bronchial secretion. The diagnosis was chronic bronchitis in 11 cases, bronchial asthma with bronchitis in 11 cases and bronchiectasis in 16 cases. The author is concerned chiefly with the 16 cases of bronchiectasis. The symptoms had persisted for from one to twenty-five years. The daily volume of sputum varied between 20 and 800 cc. Administration of sulfonamides by mouth has been found regularly effective in all cases of simple, uncomplicated bronchiectasis. The sputum was reduced in all cases. The average was a 62 per cent decrease. In the presence of atelectasis and putrid secretions the sulfonamides were much less efficient than in simple bronchiectasis. Tolerance has been about as expected except in cases known to be clinically allergic. There is no reason to believe that the lesion structure of bronchiectasis will change, though progress may be prevented by sulfonamide treatment. It is recommended that sulfonamides be used in nonsurgical cases and for preoperative therapy. It should be combined with postural drainage, bronchoscopic aspiration, climatotherapy and treatment of the sinuses.

Intravenous Pectin Solution in Shock—McClure and his associates report experiences with pectin solution in treating 275 patients who received the solution prophylactically during some major surgical procedure on the gastrointestinal tract. There were 6 total gastrectomies, 85 partial gastrectomies, 2 pancreatectomies, 1 colectomy, 11 abdominoperitoneal resections of the rectum, 14 anterior resections of the rectum and 11 Mickulicz and 12 primary resections of the colon. The remaining cases included 11 radical mastectomies, 11 neurosurgical procedures, 19 operations on traumatic and postoperative shock victims, 14 biliary tract operations and 69 miscellaneous operations. All pectin solutions were prepared by Hartman and Schelling who emphasize the care which must be observed in the preparation and standardization of pectin solutions. Each batch must be tested separately for its osmotic pressure, viscosity and specific gravity. The pH must be adjusted carefully to 7.0. In most instances pectin solution was administered as a single infusion concurrent with the operation. In a few cases it was given in two divided doses. The amount varied between 200 and 1,600 cc of 1 per cent solution, the most frequent dose being 800 cc. The authors conclude that pectin though inferior to blood or plasma appears to be of more value than glucose or saline solution in the prophylaxis of shock in extensive surgical procedures. Pectin is nontoxic and nonantigenic in the quantity of 1,000 to 1,500 cc usually required to maintain blood pressure in the presence of shock producing conditions. Untoward results appeared only after the intravenous injection of amounts in excess of 4,000 cc.

Surgical Treatment of Sciatica Due to Herniation of Intervertebral Disk—Botterell and his associates begin with a period of conservative treatment, with complete rest in bed for three weeks. If there is no improvement or if the improvement is short of enabling patients to reengage in their former duties or duties of a less strenuous character, operation may then be considered expedient. A longer period of rest in bed may be prescribed before any decision to operate is made if the improvement is moderate and continuing. Operation is not undertaken, however, if there are any other physical defects or unstable emotional or mental reactions which would make doubtful return to duty following operation. The exceptions to this policy are those whose pain is unusually severe and is not relieved by bed rest alone and those for whom operation is done to stop the rapid progression of muscular atrophy and patients with paresis of the bladder or bowel. Following operation the patient is kept in bed for from two to three weeks. His reconditioning begins in the form of tension exercises during the last few days in bed. A few days later restricted physical exercises are started and he progresses through an increasing range of activity. Fifty-one Canadian soldiers have been studied since operation. Twenty-nine have returned to full duty and 14 to sedentary duty. Eight were unfit for military duties.

Absorption of Sulfathiazole from Wounds—Waud aimed to determine the rate and depth of diffusion of sulfathiazole into the underlying tissue when applied to wounds. The influence of various bases (water miscible and fatty) on diffusion into the tissues also was studied. Rabbits were used in all experiments. Estimations of the concentration of sulfathiazole were made at different levels below the floor of the wounds and at different periods following the application of different concentrations of the drug. It was found that the higher the percentage of the drug in the base the greater was the concentration obtained in the tissues. The concentration obtained in tissues beyond 2 to 3 mm below the surface of the wound is much less than that ordinarily reached when sulfathiazole is given by mouth. Thus may not be sufficient to prevent the spread of infection and may justify the systemic administration of the drug. The level of sulfathiazole obtained in the blood when the drug is applied locally approximates that of the tissues situated at a level anywhere between 3 and 7 mm below the surface of the wound. The delivery of sulfathiazole out of a water soluble base or an oil in water emulsion takes place quite readily. When incorporated in a fatty or paraffin base and applied to an open wound, little of the drug reaches the tissues. When suspended in a liquid oil, the sulfonamide falls out and is deposited in almost the pure state on the surface of the wound or dressing.

Pork Adrenal Cortex Extract in Addison's Disease—MacBryde and de la Balze describe studies with pork adrenal cortex extract for Addison's disease. This extract has for the first time provided a means of restoring the carbohydrate metabolism to normal. The authors made studies on 7 patients with Addison's disease, which reveal that pork adrenal cortex extract has a direct action on carbohydrate metabolism and that this action is greater than that of beef adrenal cortex extract. One cc of the pork extract (in oil) represents approximately the same survival growth potency (40 rat units) as 10 cc of beef extract (aqueous). When given intramuscularly in these proportions, usually in doses of 2 cc and 20 cc respectively the pork extract tends to correct the blood sugar abnormalities of Addison's disease while beef extract exerts comparatively little such effect. In 7 patients with Addison's disease the pork adrenal cortex extract produced (1) increased absorption of glucose from the gastrointestinal tract, (2) prevention of hypoglycemia after food or glucose intake or as the result of prolonged fasting (this apparently is accomplished by increasing the glucose output from the liver), (3) increased utilization of glucose by the tissues as indicated by higher capillary and lower venous blood sugar and greater arteriovenous differences, (4) increased muscular work capacity and (5) adequate control of salt and water metabolism as well as of carbohydrate metabolism when given in small doses daily. The greater proportional effect of pork adrenal cortex extract is apparently due to its higher content of the steroids having an O or OH on C₁₁ such as corticosterone and 17-hydroxy-11-dehydrocorticosterone (Kendall's compound E). The extract seems not only to mobilize glycogen from the liver but also to increase the utilization of glucose by the muscles. This is contradictory to the conclusions of some workers who have interpreted the higher blood sugars produced in animals by cortex extracts as evidence of decreased carbohydrate oxidation. The results obtained by the authors favor these conclusions. Rather than exerting anti-insulin activity, physiologic amounts of the cortical carbohydrate hormone work synergistically with insulin to promote carbohydrate utilization; the cortical hormone causes release of glucose from the liver, the higher blood sugar then causes increased insulin secretion, which results in greater arteriovenous difference in the blood sugar in consequence of greater utilization by the muscles.

Pathogenesis of Cushing's Syndrome—Hembeker presents clinical studies in 6 cases of Cushing's syndrome as well as experiments on dogs. In 5 of the cases the hypothalamus was available for study. Hyalinization of basophil cells was found in all 5. In 4 changes in the hypothalamic nuclei particularly the paraventricular nuclei, were noted. In none of these 4 was an adrenal tumor present. In the fifth case in which a malignant adrenal tumor was found at necropsy no hypothalamic lesion was present. In the sixth case an adrenal tumor was removed at operation but the brain was not available for study. Dogs with an experimental lesion of the hypothalamus involving areas similar to those found involved in 4 cases exhibiting Cushing's syndrome show definite loss of basophil cells, with degenerative changes in the remaining basophil cells in the hypophysis. In such animals changes occur in the thyroid, in the gonads and in the islets of the pancreas of a type which serves to explain many of the symptoms of Cushing's syndrome. Experimental evidence is offered to show that at least two of the primary lesions could be expected to cause a disturbance of lipid metabolism characterized by an accumulation of fat and cholesterol in the adipose tissue of certain regions of the body. In dogs with complete or partial bilateral destruction of the caudal portions of the paraventricular nuclei there is just such an infiltration of fat and cholesterol into tissues such as the skin, the muscles, the liver and the walls of the blood vessels as occurs in persons exhibiting Cushing's syndrome. The author thinks that the conclusion now seems permissible that either an adrenal tumor or hypofunction of the paraventricular hypothalamic nuclei may be primary causes of the basophil degeneration which in turn is the immediate cause of many of the typical findings of Cushing's syndrome. Evidence is presented to suggest that the hypothalamic dysfunction may lead to hyalinization of the basophil cells through an increased effectiveness of the hormone secreted by the adrenal cortex. In this way a common pathway for influencing the hypophysis is found for the various primary disturbances which lead to Cushing's syndrome.

Paget's Disease—Reifstein and Albright call attention to the occurrence of acute atrophy of bone as a complication of Paget's disease. The bone lesions of Paget's disease are not generalized but spotty in their distribution. This fact alone is strong evidence against the disturbance being on an endocrinologic or metabolic basis. The initial lesion of Paget's disease is bone destruction, the cause of this being entirely obscure. The resultant weakness of the involved bones renders them less resistant to stresses and strains, and this leads to a stimulation of the osteoblasts and an overproduction of bone. In the skull where there are fewer stresses and strains one frequently encounters bone destruction divorced from the overproduction of bone (so called acute Paget's disease of the skull). The repair of bone by the osteoblasts is never completed, since the localized initial disorder causing bone destruction apparently persists. There results alternating destruction and repair of bone, which eventually leads to the pathognomonic mosaic structure. This mosaic appearance is due to the irregular cement lines each one of which demarcates a place where bone

destruction temporarily ceased and bone repair began. The increased bone destruction and bone repair seen in Paget's disease are closely similar to those seen throughout the skeleton in the osteitis fibrosa generalisata of hyperparathyroidism. There is one important difference in osteitis fibrosa generalisata that bone is destroyed which can best be spared, in Paget's disease bone is destroyed without regard to structure. If a bone containing Paget's disease is immobilized, as after a fracture, the lack of stress and strain, in all probability abetted by the alarm reaction of Selye, curbs the overactivity of the osteoblasts, and the serum phosphatase level an index of bone formation, falls. The initial disturbance causing bone destruction persists. There results imbalance between bone destruction and bone formation. The increased calcium and phosphorus coming from the bone leads to hypercalcemia and hyperphosphatemia. The capacity of the kidney to excrete calcium may be overtaxed, with a resulting hypercalcemia, if fluids are not forced, if the diet is not kept low in calcium and if immobilization is not kept at a minimum, a so-called chemical death from hypercalcemia may supervene. The authors describe studies on 2 patients with Paget's disease who sustained fractures. The aforementioned chain of events up to and including the hypercalcemic stage took place in these cases.

Thoracic Surgery (concluded) J. W. Strieder —p 388

Potassium Bicarbonate and Sulfonamides in Pneumonia—Ohnyst and Wolfson utilized the diuretic effect of potassium and the alkalinizing effect of its bicarbonate in treating patients with severe heart damage who were receiving sulfadiazine for pneumonia. They found that patients so treated drank somewhat more liquid than do those given sodium bicarbonate, but they excrete almost twice as much urine and eliminate over 250 cc more of retained fluid each day. By promoting excretion of retained water and sodium potassium facilitates the reestablishment of cardiac composition. The authors give potassium bicarbonate to all patients whose cardiovascular status is classified as grade 3 or 4 whenever they receive sulfonamides. Its use is being extended to milder cases as prophylaxis against decompensation. Ten Gm is given with the initial dose of sulfonamide and 25 Gm every four hours thereafter until twenty-four hours after discontinuance of chemotherapy. Although apparently of low toxicity, potassium bicarbonate is not used when severe renal impairment or adrenocortical insufficiency is suspected.

Fulminating Meningococcemia—Boger observed meningococci by direct examination of the peripheral blood smear in a case of fulminating meningococcemia that may also have been a case of the Waterhouse-Friderichsen syndrome. A woman aged 27 had been perfectly well until eight hours before admission when she appeared to have influenza. Four hours later when a blood specimen was taken, several petechiae were noted on the forearm. The following morning the patient complained of severe pains in the muscles and joints and presented a generalized purpuric rash. A blood specimen was taken for culture and examination and at the same time 10 Gm of sodium sulfadiazine was given intravenously. The temperature was 103 F, the pulse rate 110 and the respiratory rate 24. The white cell count revealed 99 per cent neutrophils. Some of the polymorphonuclear cells were found to contain phagocytized gram negative diplococci. Extracellular organisms were also observed. At noon the patient was given a 500 cc transfusion. Antimeningococcus serum was not available. Four cc of adrenal cortex extract was given intramuscularly. The purpuric spots enlarged and new petechiae appeared. That evening intracutaneous extravasations too large to be covered by the outspread hand were present over the thorax and the extremities, and extravasations of smaller size were present on the face. The patient could not be roused. She gradually went into a state of vasomotor collapse and died. Permission for necropsy was

not granted so that doubt remains whether there were adrenal hemorrhages. The diplococci seen in the blood smears were cultured from the blood stream and found to be meningococci. The Waterhouse-Friderichsen syndrome is an overwhelming septicemia that produces purpuric subcutaneous extravasations and bilateral adrenal hemorrhages. Although meningococcal infections usually produce this syndrome, overwhelming sepsis due to other organisms occasionally gives rise to similar adrenal hemorrhages. Not all patients who die with the clinical picture of the Waterhouse-Friderichsen syndrome present adrenal hemorrhages. Hence it seems ambiguous to use the term 'recovery' in speaking of the Waterhouse-Friderichsen syndrome, since the adrenal hemorrhages can be inferred only if the patient recovers. Clinically the term "fulminating meningococcemia" seems preferable to "Waterhouse-Friderichsen syndrome" and the latter should be restricted to pathologic discussions.

Penicillin in Compound Fractures—Carpenter and Mech state that the compound fracture is the major problem in the orthopedic casualties returned to this country. Efficient first aid, plasma, blood transfusions, the sulfonamides and the open wound treatment have served to minimize infection and mortality. Penicillin is a more effectual antibacterial agent than the sulfonamides in both the prevention and the cure of infection. It has likewise proved valuable in the prevention of reinfection following reconstructive operative procedures. This factor has made it possible to perform major surgery sooner after complete wound healing than had been the case with the use of the sulfonamides. Penicillin therapy must be recognized and accepted as an adjunct only in the management of a surgical problem. Penicillin cannot replace a well planned surgical program. Penicillin assumes the role of only an effective antibacterial agent in the treatment of compound fractures.

Clostridial Infections (Gas Gangrene)—Dowdy and his associates investigated gas gangrene in more than 1,400 dogs in which the disease was experimentally produced. A variety of agents have been tested, such as roentgen therapy, subcutaneous and intramuscular oxygen, sulfadiazine, sulfathiazole, sulfanilamide, penicillin and pentavalent antitoxin. The infectious agents were virulent cultures of *Clostridium perfringens*, *Clostridium septicum*, *Clostridium novyi* (two strains) and *Clostridium sordelli*, employed either singly or in combination. The combined clostridial inoculums, in addition, contained a strain of *Staphylococcus aureus*. Experimentally, sulfadiazine has proved to be extremely efficacious in its prophylactic use against *Cl. perfringens*, *Cl. septicum* and *Cl. sordelli* infections in dogs when the disease is produced by individual pure cultures and when produced by a mixed culture of these same organisms contaminated by *Staph. aureus*. None of the sulfonamides were found to be effective against the disease when produced by *Cl. novyi*. Therapeutically sulfadiazine is far less effective, but from their limited clinical use of this drug the authors feel that it has been of value. Experimentally penicillin and pentavalent gas gangrene antitoxin are both powerful therapeutic agents. The latter is the more valuable of the two if used late in the disease because of its toxin neutralizing effect. Antitoxin must be used in large amounts and the entire dose given within a relatively few hours. The possibility of an anaphylactoid reaction must be borne in mind. The patient should be tested for sensitivity and if he is sensitive desensitization should be carried

out During the period of desensitization, sulfadiazine or penicillin should be used, preferably the latter. The authors found no contraindication to combined therapy with all three of the agents discussed. Rather, they have an additive effect.

- *Influenza Epidemic of Winter of 1943-44 in United States Preliminary Summary Dorothy F Holland and S D Collins—p 1131

Influenza Epidemic in Winter of 1943-1944—Holland and Collins report an outbreak of a mild type of influenza which started in Minnesota and the Great Lakes region about the middle of November 1943. From the North Central region the epidemic spread eastward to New England, the Middle Atlantic states, Kentucky, Virginia, West Virginia, Delaware and Maryland, outbreaks being reported subsequently in the Mountain and Pacific states, the Southeast (Central and Atlantic) and, finally, the West South Central states. The Army as well as the civilian population experienced the epidemic. The tendency of influenza to occur in pandemic form "in cycles with intervals of several decades" led to concern that the 1943 outbreak might assume the characteristics of the 1918 pandemic. This apprehension was increased by the fact that in November, when the first indications of an outbreak were observed in this country, influenza had already attained epidemic proportions in England and Wales. However, the sharp rise in influenza deaths in the 126 large cities of England and Wales in November and December was found to be due not to the virulence of the causative organism but to a high case incidence. The subsequent course of the outbreak in the United States as well as the experience of other countries gives no evidence of a recurrence of the severe type of influenza observed in the 1918 pandemic. Characteristic features of the disease were the sudden onset, moderate prostration fever and general pains, followed by great weakness. The duration was between three and five days. The laboratory evidence indicates that the outbreak was probably largely due to influenza virus A. The death rate from all causes during an influenza epidemic is an especially significant measure of its severity, the excess mortality relative to that in a nonpandemic period representing deaths associated with the epidemic. They found that for a group of ninety large cities the mortality from all causes in excess of the normal expectancy during the eleven weeks from Nov 21, 1943 to Feb 5, 1944 amounted to 50 per hundred thousand of population. This

figure may be compared with total excess rates from all causes for a group of thirty-five large cities of 65 per hundred thousand for the epidemic of 1928-1929, 48 for that of 1926, 50 for that of 1923, 34 for that of 1922, 125 for the epidemic of 1920 and 598 for the pandemic of 1918-1919. Thus the current outbreak was larger than any epidemic since 1928-1929 but caused only about 8 per cent as many excess deaths in the United States as the 1918 pandemic. An interesting feature of the epidemic in England and Wales was the action taken to relieve the acute shortage of civilian medical personnel. An arrangement was made for the deferment from induction into the services of some 300 junior house physicians. In addition, the Royal Army Medical Corps made available hundreds of army doctors to assist in the care of influenza cases among civilians, representing the first instance of such cooperation between military and civilian medical personnel.

Adenoma of Bronchus—Bronchial adenoma is a true tumor and the associated bronchiectasis, rather than being the cause of the growth, results from the long-standing obstruction of a bronchus. The most generally held view is that bronchial adenomas arise from the duct epithelium of the bronchial mucous glands. The adenoma is a smooth, round or oval, pinkish tumor. The intrabronchial growth is frequently polypoid and may be pedunculated. In some instances, however, it is flat, sessile and attached by a broad base. There is often extension through the bronchial wall, with formation of an extrabronchial mass which may be larger than the intrabronchial portion. Although adenoma of the bronchus almost always remains benign as far as lethal metastasis is concerned, its effects on the lung are extremely serious and in many instances ultimately cause death. The tumor grows slowly and gradually occludes the bronchus. During this process repeated infections occur distal to the obstruction, and sooner or later the portion of lung involved is destroyed by recurring suppuration. Bronchiectasis is regularly produced and more acute infectious processes such as suppurative pneumonia, pulmonary abscess and empyema may occur and eventually prove fatal. A diagnosis of bronchial adenoma is usually easily established by roentgenologic and bronchoscopic examination, once the condition is suspected. The chief reason for differentiating between bronchial adenoma and bronchiogenic cancer is that adenoma of the bronchus has a prognosis quite different from that of cancer and therefore permits the employment of a more conservative plan of therapy in properly selected cases when radical resection would be attended by a great risk. Seven cases are presented to illustrate (a) the typical clinical features of intrabronchial adenoma (b) bronchial adenoma with an extrabronchial mass, (c) the various types of roentgen examination used in the diagnosis, (d) the value of body section roentgenography in the delineation of the tumor and in following the effects of treatment and (e) the results of various types of therapy in the several cases namely no treatment, local extirpation and pulmonary resection.

Fractures of Carpal Scaphoid—Dickson and Shannon present the results of a study of 257 cases of fractured carpal scaphoids occurring in approximately three years in the Canadian army overseas. The most common fracture is a transverse one through the body of the bone, usually occurring at the waist or the center of the body. The statistical analysis of the 257 cases shows that 196 involved the waist of the scaphoid, 38 involved the proximal pole and 23 involved the tubercle. The most important problem of fracture of the scaphoid is early diagnosis. The authors analyze the results of treatment with regard to the time of diagnosis. Fractured scaphoid diagnosed early and properly treated will almost invariably unite. By proper treatment is meant reduction of displacement, if present, and uninterrupted immobilization with the wrist in extension and radial deviation until union occurs. It is probably true that a fractured scaphoid never unites if left untreated. Will such fracture if left untreated invariably lead to a painful wrist in later life? Some patients carry on for long periods with only a minimum of discomfort. Some are symptom free for a long period, and when injured a second time their symptoms are relieved by a short period of immobilization. That some of them develop disability in later life is undoubtedly true. How to obtain union consistently in these late diagnosed fractures within a reasonable time is still an unsolved problem. Immobilization was often unsuccessful in the cases presented in this report. The criticism might be made that the immobilization was not carried on long enough. There is danger of persisting in this form of treatment too long without evidence of progress toward union. Complete or partial excision is of no use in these fractures. Union may be obtained by a grafting operation, but this is difficult. The late fracture with degenerative arthritis is an arthritis problem and must be treated as such. Union of the fracture will not relieve the symptoms, and palliative treatment is all that can be offered, fusion of the wrist being the last resort and warranted only by severe disability. The patient with a fractured scaphoid may be able to carry on his occupation during the long period of treatment. Often, however, this is impossible and there is serious economic loss.

Vagotomy in Peptic Ulcer—Weinstein and his collaborators report 6 clinical cases in which vagotomy was performed either alone or in conjunction with some other operative procedure. Most of these cases had not responded to ordinary measures. In 3 cases the lesion was a gastroduodenal ulcer following partial gastrectomy, in 2 it was a duodenal ulcer, and in 1 there existed severe functional complaints without demonstrable organic lesion. In only 2 cases was complete vagotomy attempted, but in neither of these was it achieved. The validity of the insulin test as an index of persistent vagal innervation

was upheld by the studies in these cases. In none of the cases was evidence of beneficial therapeutic effect obtained. Gastric vagotomy alone cannot be recommended as a therapeutic procedure.

Corrosive Gastritis—Meyer and Steigmann state that the surgeon usually sees these patients when they begin to suffer from the sequelae of corrosive gastritis. These sequelae are manifested by symptoms of pyloric obstruction. Since they may not be evident until many months following the intake of a corrosive substance, the patients often do not associate their present symptoms with the past mishap. Therefore the patient should be asked directly as to a possible intake of a corrosive substance. The history is of great importance in corrosive gastritis, because except for the history of ingestion of a corrosive substance there is rarely any other way by which it can be diagnosed before operation. In many instances the diagnosis may not be made by the surgeon even at operation if he is not aware of such a condition. It is important to differentiate between corrosive gastritis and carcinoma not only from the point of view of prognosis but also from the point of view of treatment as corrosive gastritis requires different preparation and operation. In many cases of corrosive gastritis two stage operations may be necessary, i. e. primary jejunostomy and secondary gastroenterostomy at a later date, while in carcinoma this is rarely advisable. The patient with corrosive gastritis does not present an emergency case and all possible measures should be taken to build him up before surgery is undertaken. Gastroenterostomy rather than resection may be done, as the dangers of secondary gastrojejunostomy ulceration are minimal since there is no free acidity. Patients with corrosive gastritis have to be prepared carefully and for a long time, if necessary, by jejunostomy feedings, for the final operation on the stomach. In some cases with very small fundic pouches "sham feedings" have to be given in order to distend this portion sufficiently to permit the gastroenterostomy. The authors present representative histories of 4 patients with corrosive gastritis seen at the Cook County Hospital.

Posterior Mediastinal Gout—Partially intrathoracic gouts occur relatively often. Completely intrathoracic gouts are much rarer. The rarest of the intrathoracic gouts is the type found in the posterior mediastinum. Only 6 such cases have been previously recorded. The case here reported by Mora and his associates is the seventh to be recorded. A woman aged 55 was admitted to the hospital in November 1942 complaining of increasing weakness, nervousness, palpitation and weight loss. She had not been feeling well for about eight years, having noted increasing fatigue on slight exertion, profuse perspiration, heat intolerance and tremor of the fingers. From time to time she would have bouts of nervousness, weakness, irritability and palpitation. She had been studied by several doctors, all of whom found on x-ray examination of the chest a large shadow occupying the right upper lung field. She was advised to do nothing about this mass. Examination by the authors disclosed tremor of the fingers, basal metabolic readings between +45 and +51 and a large globular mass occupying the right upper thoracic cavity, on lateral views this mass was seen to lie in the posterior mediastinum. The diagnosis at this time was thyrotoxicosis, and the mass was believed to be a large intrathoracic gout. At operation the neck was opened through the usual collar incision and the strap muscles were separated. Preliminary exploration revealed no thyroid tissue in the neck. On further dissection a small cystic lobe was found on the left, just at the superior thoracic aperture. This was easily removed. On the right, a thin attenuated pole was found just below the level of the first rib, this was secured and divided between ligatures. On further exploration a large mass was encountered posteriorly, lying entirely within the thoracic cage. On careful finger dissection, hugging the margins of the mass and with gentle traction upward, the tumor was gradually freed. A hemostat was then plunged into the mass, and the liquid and jelly-like contents were removed by suction. This procedure permitted narrowing of the transverse diameters of the thoracic gout, following which it was easy to deliver the entire mass. The patient was discharged in good condition on the tenth postoperative day. One year after operation the basal metabolic rate was +6.

Delayed Mustard Gas Keratitis.—Since 1937, when the condition of delayed mustard gas keratitis was first beginning to be recognized, Mann has examined a relatively large number of cases. 84 have passed through the contact lens clinic at Moorfields. All the patients gave a history of exposure to mustard gas in 1917 or 1918. The diagnosis was made on the history and on the finding of the typical mustard gas scars with corneal degeneration, varicose conjunctival and corneal vessels and avascular scars on the interpalpebral conjunctiva. The patient does not generally connect the delayed keratitis with the exposure to gas. Most of them did not notice anything until the ulceration stage began. Only 8 of the patients stated that the sight of one or both eyes had never been so good as before the gassing and that they had had some sort of eye trouble ever since. The recurring ulcers heal but tend to leave faceted scars, which gradually diminish visual acuity. Repeated attacks and a slowly deteriorating visual acuity, relieved by wearing contact lenses, is typical of roughly 46 per cent of the cases. What their subsequent fate will be is not yet known. That wearing contact lenses does not entirely prevent breakdown and further deterioration of sight seems certain, but it is equally certain that in a number of cases retention of visual acuity and continuance in work has been made possible for many years. Patients with mustard gas lesions usually have very good tolerance for contact lenses, both on account of the relative insensitivity of their corneas and on account of the vast improvement in visual acuity, which acts as a spur to success. Thirty-nine of the 84 patients wear the lenses with comfort during the working day. Of these 39 patients 20 have had relapses since wearing the lenses. Thirteen of these have had far fewer relapses than before wearing the lenses. Small shallow ulcers heal fairly quickly with mild mydriatics and heat. Deeper ulcers, discharging cholesterol and fatty debris from the base, take longer to heal and may require tarsorrhaphy. Superficial plaques, raised from the surface, of degenerative material may mechanically interfere with the wearing of a contact lens and should be scraped off.

Scurvy.—McMillan and Inglis review observations on 53 patients with scurvy. There were 48 men and 5 women. The patients ranged in age from 41 to 82 years. 43 were over 65. The disease observed was typical bachelor's scurvy. There were three root causes. First and most important was ignorance, mainly in men of the need for potatoes and vegetables

in the diet. Second was apathy leading to neglect of the same items because they required preparation and cooking. Third was poverty, making it impossible to buy an adequate diet or live anywhere but in the worst type of lodging with poor cooking facilities. The first factor was not so significant in peacetime, as many countered it by eating fruit. Wartime scarcity of fruit without a compensatory increase in the intake of potatoes and vegetables resulted in such persons developing scurvy. It is suggested that as long as the scarcity of fruit exists the concessions at present enjoyed by children and expectant mothers should be extended to the elderly. Clinically the only unusual complaint was lumbago, which probably was the result of small deep hemorrhages in the muscles of the back. Although in no patient was the blood picture completely normal in some it was nearly so, and agreement is reached with the opinions of others that (a) anemia and scurvy need not coexist in man, (b) when they do coexist the anemia often bears no relation to the extent of the hemorrhages or the plasma ascorbic acid content and (c) the anemia is varied in morphologic type being mainly normocytic. The authors suggest that the anemia of scurvy is due to a complex deficiency, with vitamin C acting only as an adjuvant.

Bleeding Gums and Ascorbic Acid.—Stamm and his associates investigated the incidence of bleeding gums in the Royal Air Force and aimed to assess the value of ascorbic acid in the treatment of this condition. All personnel available were examined, except those already taking ascorbic acid, those being treated for acute ulcerative gingivostomatitis and those with no teeth. All those included in this experiment had been living on service rations for six months or more. The gums of the lower jaw were examined for bleeding after digital massage. Alternate members of the group with bleeding gums were given ascorbic acid tablets and dummy tablets flavored with tartaric acid. The dose of ascorbic acid was 200 mg daily for seven days, followed by 100 mg daily for fourteen days, the dummy tablets were similar in appearance and taste and were given in similar numbers. At the end of the experimental period all subjects given ascorbic acid and dummy tablets were reexamined. The original notes were not available to the examiner so that he could not be influenced by his previous observations or by a knowledge of which tablets had been given. The ascorbic acid content of the food served to the airmen in the messes was determined by the dichlorophenol-indophenol technique. The average amount of ascorbic acid present in the food served to airmen was 25.8 mg per man daily during October and November 1941 and 16.8 mg during March 1942. On examination of 2,962 personnel, 588 (19.8 per cent) were found to have some degree of bleeding of the gums, a similar incidence being found in the autumn and spring and at each of the stations. No greater improvement in the gum conditions was obtained by treatment with ascorbic acid than with control tablets. Observation of 600 personnel over a six weeks period showed that there was a large normal variation in the degree of bleeding of the gums, irrespective of treatment. Those having "sponginess" as well as bleeding of the gums showed no greater improvement with ascorbic acid treatment than with dummy tablets. Patients' personal opinions as to the efficacy of treatment bore no relation to the objective signs.

Treatment of Rheumatoid Arthritis with Bismuth. A. H. Douthwaite—p. 276

Homologous Serum Jaundice.—According to Bradley and his associates the occurrence of jaundice in man after the administration of human blood products is now a well recognized phenomenon. The jaundice, which is of hepatic origin, is readily distinguished from the hemolytic icterus which may arise immediately after transfusion with incompatible blood or out of date stored blood. Clinically it is similar to if not

indistinguishable from, epidemic hepatitis (catarrhal jaundice), but the incubation period is unusually long—commonly from two to three months, in contradistinction to the twenty to forty day period in epidemic hepatitis. A high incidence of this jaundice has been observed among 71 subjects during the course of an investigation into allergic reactions to human serum. All these subjects received pooled human serum from a single batch (No 034). Subsequently icterogenicity was confirmed by the results of the deliberate administration of this batch to 4 volunteer patients with rheumatoid arthritis in whom it was desired to produce jaundice for therapeutic reasons. Forty-seven subjects received intradermal skin tests with batch 034. Nine subjects received intradermal skin tests and serum transfusions with batch 034. Nineteen received skin tests or transfusions or both with batch 034 and, in addition, tests or transfusions with other human material. Of these, 7 were allergic subjects, 8 were nonallergic controls and 4 were the patients with rheumatoid arthritis. All except 2 subjects were followed up for at least one hundred and fifty days after exposure. Of the 47 patients who had received batch 034 only as skin tests, 26 developed jaundice. Similarly, of the 9 who had batch 034 only as skin tests and transfusions 5 developed jaundice. Of the 19 patients who received other materials as well as batch 034, 11 developed jaundice. The authors point out that the cases of jaundice in the present series had been regarded as "catarrhal jaundice" and the association with the administration of blood products was at first not recognized. The diagnosis of homologous serum jaundice was established only by the follow-up. Jaundice occurred in 57 per cent of the persons exposed. The dose of homologous serum administered varied from 0.1 to 1,200 cc. The severity of the disease was not related to the dosage of serum given or to the route of administration.

Acridines in Septic Wounds.—According to Poate 5-aminoacridine is *stable*, is *stable in solution*, has a *pH* of 6 and is *innocuous* to human tissues in 1:1,000 solution. In an Australian general hospital 5-aminoacridine was chiefly used but 2:7-diaminoacridine was also tested. The latter was not favored in the wards because of its staining propensity. Both these acridines were applied as powders (alone or with sulfanilamide) and in solutions of varying strength, but finally 1:1,000 became the standard concentration. When there was a pyocyanous infection 2 per cent acetic acid was added. To get the best results all sequestrums and sloughs must be removed, drainage of deep wounds must be efficient, immobilization of fractures must be adequate and the patient's hemoglobin must be kept as near normal as possible. Closed plaster treatment

was abandoned. The effect of the two acridines was that the wounds soon became surgically clean, healthy granulations promoted rapid healing. All purulent discharge ceased within a few days, thus relieving the patient of a continuous drain on his tissue proteins. As a result, transfusions were no longer necessary, appetite returned and patients put on weight. In no case treated by these two acridines was there a gravitational abscess, secondary hemorrhage or cellulitis. The authors review clinical experiences with 5-aminoacridine and 2:7-diaminoacridine in 120 cases, including 24 suppurating gunshot wounds of bone. The results have been very good. In all but 5 cases sepsis was immediately controlled. For general use in wards 5-aminoacridine is preferred because it does not stain fabrics and tissues. Where there is gross established sepsis, the wound may be irrigated with an aqueous solution of 5-aminoacridine (1:1,000) through Carrel tubes. For other purposes an emulsion may be made, or acridine in powder form may be mixed with sulfanilamide (1:10 to 1:40). Recent wounds associated with compound fractures have been treated with this powder after debridement and then closed by primary suture. 5-aminoacridine seems to be particularly effective against hemolytic staphylococci and appears to favor bone repair.

*Rh Factor. D. Invernizzi—p. 396.

Rh Factor.—Invernizzi states that the percentage of positive distribution of the Rh factor is greater in mestizo people, Indians and colored people than in white people. The proportion is from 93 to 99 per cent in the former and 85 per cent in the latter. The presence of the Rh factor in the erythrocytes is determined by the reaction of 0.01 cc. of a 2 per cent solution of erythrocytes in isotonic solution of sodium chloride containing 0.02 cc. of anti-Rh serum, after contact of both constituents in a test tube for one hour in the water bath at a temperature of 37°C. Fresh blood is used because of the fact that the Rh factor is easily destroyed in the erythrocytes. A positive macroscopic reaction is shown by rugosities in the border of the globular sediment in the test tube. Moderate positive reaction with moderate agglutination is observed microscopically. Specimens of well known positive Rh and negative Rh blood are used as control tests. Repeated transfusion of blood from Rh positive donors to Rh negative individuals may provoke anti-Rh agglutinins in the blood of the latter. A test is performed after repeated transfusions for ascertaining the presence of isoimmunization or lack of it before further transfusion. The danger of post-transfusional reactions is acute in pregnant women who may have developed a condition of isoimmunization through the presence of the Rh factor in the blood of the fetus. The hydropic, acute icteric and congenital anemic forms of erythroblastosis fetalis are due to the presence of the Rh factor in the infant's blood. The condition may be found in one of two twins and not in the other in cases of heterozygotic transmission of the Rh factor by the father. The author advises use of negative Rh blood for transfusion to infants with any type of erythroblastosis fetalis, as well as to mothers of erythroblastic infants and when repeated blood transfusions are given. Plasma should be used in emergencies.

- *Pernicious Anemia and Hepatic Cirrhosis. M. R. Castex, E. S. Mazzei and J. Remolar—p. 378.
New Aspects in Therapy of True Anthrax. M. Gomez Fresno—p. 426.

Pernicious Anemia and Hepatic Cirrhosis.—Castex and his collaborators describe two types of macrocytic hyperchromic anemia complicating liver cirrhosis. One type is that of pernicious-like anemia. It is a frequent complication of liver cirrhosis and disappears on liver therapy. The second type is a true pernicious megaloblastic anemia of the Biermer-Addison type. It is a rare complication of liver cirrhosis and does not respond to liver therapy. It has an acute course and fatal prognosis.

Book Notices

X Ray Examination of the Stomach A Description of the Roentgenologic Anatomy Physiology and Pathology of the Esophagus Stomach and Duodenum By Frederic E Templeton MD Head of the Department of Roentgenology the Cleveland Clinic Cloth Price \$10 Pp 116 with 297 illustrations Chicago University of Chicago Press London Cambridge University Press 1941

The time devoted to the x-ray examination in diseases of the digestive tract often seems to be in inverse ratio to the importance of the procedure. In this admirable book the technique of a detailed, painstaking search for abnormalities of the esophagus, stomach and duodenum, done with full consideration for the serious consequences which may result from the interpretation of the findings, is portrayed. This is a monograph representing essentially the experience of the author and his colleagues at the University of Chicago, but there are numerous quotations from the literature, and the bibliography is extensive. The most valuable portion of the book is the detailed description of the methods of x-ray examination of the upper digestive tract, with particular attention to the "filming fluoroscope." The technique of fluoroscopy is well described and illustrated by means of films exposed under fluoroscopic guidance. The descriptions of the normal variations of these structures and most especially of the physiology and pathology of the esophagus are especially instructive. The grouping together of the abnormalities of the esophagus, stomach and duodenum under such headings as inflammations, ulcer and neoplasm rather than treating each individually is somewhat forced, as the x-ray manifestations of the pathologic conditions of these organs are not especially similar. Likewise the placement of the section on differential diagnosis at the end of the book far removed from the original descriptions makes for some repetition. The illustrations are abundant, well chosen and well reproduced. Few exceptions can be taken to the author's conclusions. The designation of the term "phytobezoar" rather than "trichobezoar" for a hair ball is obviously an oversight. The contributions of Lewis Gregory Cole to the x-ray examination of the digestive tract are insufficiently stressed. The book suffers from the author's lack of sufficient experience or reluctance to offer an opinion when he has not had personal contact with a method or a problem. These criticisms are minor. The book as a whole is one of the finest contributions to roentgenologic diagnosis in the past decade and should be read assiduously by every physician who has interest in the diseases of the upper digestive tract.

Conference on Tuberculosis Isolation Sponsored by the California State Department of Public Health Held at Los Angeles March 20 1943 [Editor Edward Kupka MD] Paper Various pagination Los Angeles [n d]

This mimeographed, paper bound release is a virtually complete summary of the conclusions of the Conference on Tuberculosis Isolation sponsored by the California State Department of Public Health at Los Angeles on March 20, 1943. It is an effort to mobilize public opinion in support of the legal requirement not common in many states providing for enforced isolation of tuberculous patients with open lesions who fail or refuse to heed their responsibilities for preventing the spread of infection. Experience in Los Angeles County and the opinions of health officers, judges, sanatorium personnel and representatives of the state attorney general's office are set forth at length. This report should be valuable to tuberculosis control officers and, to a lesser extent, should be of interest to the voluntary tuberculosis associations.

First Hospitals in Tulsa By Fred S Clinton MD FACS Reprinted from The Chronicles of Oklahoma Vol XXII Number 1 1944 Paper Pp 28 with illustrations Oklahoma City 1944

The author has preserved for the Chronicles of Oklahoma the story of the first hospitals in Tulsa, beginning in 1900 when the city had a population of only 1,390. It is principally a story of three hospitals in whose establishment and development the author had an active and directing part. The first was organized in 1900 a six room isolation cottage necessitated by the occurrence of a smallpox epidemic. Six years later the Tulsa Hospital Association was formed and a general hospital established which also brought to this community the first training

school for student nurses. The third hospital included in this historical account the Oklahoma Hospital was chartered Dec 11 1915. Other early hospitals are also mentioned with the hope that other writers of local history will at some future time furnish an extended account of the contributions and services of these institutions.

In writing this article the author has drawn from his own experiences and records and has also introduced documentary evidence of many of the events of this early hospital period. His work is of interest not only from a historical point of view but as a record of hospital problems and needs that occur in a new and growing community.

Dust Hazards in Australian Foundries By A A Ross B A G S and N H Shaw B A G S Technical Report No 1 Industrial Welfare Division Department of Labour and National Service Commonwealth of Australia Paper Pp 43 Melbourne 1943

This pamphlet gives the results of a study of the dust hazards in the various processes in Australian foundries sets up standards of permissible dust limits as determined by the Owens jet dust counter and makes recommendations for control in those operations found to have an unsafe concentration of dust. The review of the literature is merely that supporting the occurrence of pathologic changes in the lungs from exposure to industrial dusts. The authors discuss the recognized limitations of the Owens jet dust counter as compared to the Greenburg-Smith impinger. They apparently reached the conclusion that the practicality of the former outweighed whatever inaccuracies it may have after studying atmospheric conditions with both around the various foundry processes. They state that there was no definite correlation in the findings of the two, however, they do give standards of dust concentration as determined by the Owens jet dust counter which they feel are within safe limits for exposure of the workmen. They arrived at the inevitable conclusion that environmental conditions in Australian foundries as pertaining to dust should be improved.

Twenty Second Hospital Yearbook 1944 Hospital Purchasing File Directory of Hospital Products Manufacturers Catalogs Editorial Reference Section Twenty second edition Boards Price \$2.50 Pp 91. Chicago Modern Hospital Publishing Co Inc 1944

This is an excellent reference book on hospital buying. It has an extensive directory of hospital products covering 360 pages with supplementary catalogues on clinical and scientific apparatus, general furnishings, food service equipment, laundry facilities and supplies, construction materials and plant equipment. An editorial reference section contains comprehensive check lists and other valuable information essential in the planning of hospital departments and services. The administrative officers and departments of hospitals will find this book a valuable and convenient source of reference. Its usefulness is further enhanced by a complete index of catalogues and advertisements, an alphabetical list of manufacturers and distributors and lists of hospital associations and national agencies serving the hospital and allied fields.

Handbook of Nursing in Industry By M Cray Macdonald RN Cloth Price \$2.50 Pp 226 Philadelphia & London W B Saunders Company 1944

This is a textbook of moderate detail dealing with the various functions of the nurse in industry. The descriptions and discussions in the twenty-six chapters include those phases which should be included in a well rounded program. Special attention is called to the modifications of a program in a bank, department store, restaurant and a mill village. The philosophy and practical experience of the author add materially to the stature of the book. It should find wide use in the added emphasis that is being given to industrial health education for nurses both graduate and undergraduate.

Red Lights on the Horizon By H Ameroy Hartwell Boards Price \$1 Pp 22 Illustration by Gladys Richecek Boston Bruce Humphries Inc 1944

Here is a new poem by Dr Hartwell calling attention to the early signs and symptoms of disease. Whether or not this is the best technique to cause patients to see their physicians for early diagnosis is a matter of considerable doubt. Nevertheless the author must have had a good deal of pleasure in writing the poem.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DEFECTIVE SPEECH AND POSSIBLE LEFT HANDEDNESS

To the Editor—A 5 year old girl who appears to be normal in every other respect has a tendency toward left handedness and defective articulation. The flow of speech is smooth but she substitutes y for i, d for sch or g and w for r. Thus Mary had a little lamb becomes in her rendition Mawy had a yitta yamb the red school bus becomes the wed dool bus and a green chair becomes a "deen" one. I once heard a professor of physiology who was afflicted with stammering attribute his difficulty to his being left handed but compelled to use his right hand thus interfering with the speech center of Broca. When the child under consideration is eating she is seen to carry the fork sometimes in her left hand sometimes in her right. Because of the observed tendency for her to use her left hand would it be advisable as a preliminary to attempting to correct her defective articulation, to encourage her to use her left hand as the dominant one? Any other suggestions as to methods of correcting her speech will be appreciated.

M. D., Alaska

ANSWER—It is not unusual for children of 5 to demonstrate this type of defect. Some children, although normal in other respects, are slow in learning the language skills—perhaps because of a slower maturation of the language centers of the cerebrum. They will often, as the child in question apparently does, substitute simple speech sounds for the more complex or sounds made at the front of the mouth for sounds made farther back. (Sight plays an important role in the acquisition of speech and the child usually learns first the sounds whose essential movements can be easily seen and imitated, for example p, b, m, w. Conversely, he learns last the sounds whose essential movements are made farther back in the mouth and cannot be easily seen, such as r, k, g, ng.)

The tendency to ambidexterity may or may not be significant. It would be best to make no attempt to establish the dominance of one hand. Given time the child will no doubt do this herself. In regard to correcting the speech defect, a daily period of speech drill is recommended. The defective sounds should be isolated and pronounced alone until the child can produce them correctly. Later they can be incorporated into simple sound combinations and eventually into familiar words and phrases.

THYROID OR PITUITARY DEFICIENCY

To the Editor—A girl of 18 is overweight and losing her menses there is almost no flow and occasionally she skips a month. The basal metabolic rate is -23. If this case is one of pituitary origin is there any treatment and cure? She will receive some thyroid medication. Is it true that in a pituitary case cancerous changes always develop later in the abdomen or pelvis?

M. D. New Jersey

ANSWER—It is difficult to decide whether irregular and scanty menstruation, obesity and a low basal metabolism are due to thyroid deficiency or pituitary disorder without having other information. Usually the determination of serum cholesterol would be helpful, since in thyroid deficiency not under thyroid treatment the cholesterol will be well above normal levels but in pituitary deficiency cholesterol is below the normal upper limits. It may be wise to try thyroid cautiously with basal metabolism check, to use a carefully limited diet to control the weight and gonadotropic pituitary or pregnant mare's serum concentrate may be tried subsequently if this does not show a distinct tendency to correction of the difficulty.

There is no known reason to suspect that pelvic or abdominal malignant disease would follow in case this is a pituitary deficiency.

FOUL TASTE IN MOUTH DURING PREGNANCY

To the Editor—Two years ago I rendered obstetric care to a patient who developed an intense foul taste in the throat in the third month of gestation and this persisted until a day after delivery. Careful investigation of the sinuses, nose, mouth and throat proved negative. The patient is again pregnant and after six weeks gestation has this same intense foul taste. Medication has not alleviated it. I would appreciate an opinion.

M. D. New York

ANSWER—The search for an organic cause of the poor taste in the mouth should include a careful examination of the teeth. Decay in a tooth is often the focus of a bad taste. If no cause is found a mouth wash of dilute hydrogen peroxide or 5 per cent potassium chlorate may help to control the discomfort. In rare instances the cause may be psychic in origin and little can be done toward its therapy.

OSTEOCHONDROSIS OF NAVICULAR (KÖHLER'S)

To the Editor—A girl aged 2 years in good health, began to stumble, fall and walk unsteadily with a limp in the left leg. Complete investigation revealed no abnormalities excepting x-ray finding of irregularity and condensation of the left navicular consistent with the diagnosis of osteochondrosis or Köhler's disease. Could you advise concerning current opinion as to etiology, therapy and prognosis?

Jack H. Tabor, M.D., Dailey, W. Va.

ANSWER—In the large majority of cases of Köhler's disease, or osteochondrosis, of the navicular bone, there is little pain or disability. A thorough search should be made to determine if there is any other existing condition which could account for the stumbling, unsteady walk and limp. The treatment of Köhler's disease is simple surgery should not be done. About all that one can do is provide a little support in the shoe to hold up the longitudinal arch. Saddler's felt or piano felt pasted in the shoe is as good as anything.

TESTING FOR ALLERGY TO CATGUT

To the Editor—I have come across several patients whom I have suspected of being sensitive to catgut. With the help of the allergy department I made up solutions of plain and chromic catgut in the following manner: I allowed a strand of each type of catgut to soak in absolute alcohol in the proportions of 10 to 1 for forty-eight hours. The allergist then made me several dilutions of 1:100, 1:10 and full strength using Coca's solution as a diluent. I tested several patients with these solutions and obtained 2 plus reactions in several. However on further control testing I found that the absolute alcohol itself causes a similar reaction. New solutions were then made up by soaking the catgut in Coca's solution for several days without the alcohol and so far all my intradermal tests have been negative. Would you kindly tell me if an adequately potent extract of catgut can be obtained by the latter method of using just Coca's solution?

M. D. North Carolina

ANSWER—Catgut is specially prepared tendinous tissue. This is not soluble in water or neutral saline solution. Allergy to catgut, therefore, is presumably due to the presence of minimal amounts of soluble proteins in improperly prepared catgut. To obtain a solution of this material the catgut might be scraped with a razor blade or sharp edge of a broken piece of glass. The finer the shavings, the more likely soluble material may be obtained. The fine shavings may then be soaked in 0.2 per cent sodium carbonate for several hours or over night. A mechanical shaker or grinding in a mortar will help. After filtering, the solution should be neutralized with diluted hydrochloric or acetic acid to a pH of about 7.0. It may be necessary to keep the material slightly alkaline, i.e., about 7.4, in order to avoid precipitation of the protein obtained by extraction. Therefore only a small portion of the solution should be neutralized at first to determine the pH at which precipitation begins. The rest of the solution should be neutralized to a point where no precipitation will occur.

Phenol is then added as a preservative to a concentration of 0.5 per cent. After this the material is filtered through a Seitz or Berkefeld filter for sterility. The material must then be tried on a half dozen normal patients to make sure that it is not a primary irritant which will produce false positive reactions when 0.02 cc is injected intradermally. If it proves to be irritating it should be diluted with isotonic solution of sodium chloride to make a 1:10 or 1:100 dilution as necessary, to avoid any primary irritating properties.

LEUKOPENIC INDEX IN ALLERGY

To the Editor—I have only recently read Dr. L. P. Gays' article about the leukopenic index in *The Journal* of March 21, 1936. Please inform me if subsequent events have shown the leukopenic index method to have as much practical value as was hoped for. If so is there any later helpful article available on the subject that gives further information on the method?

R. D. Holt Jr., M.D., Meridian, Texas

ANSWER—The technique, pitfalls and value of the "leukopenic index" in allergy are adequately discussed by the late Dr. Warren T. Vaughan in his book "Practice of Allergy," St. Louis, C. V. Mosby Company, 1939. Vaughan first suggested the leukopenic index as a method of study of food allergy. It is a modification of part of the liver function test suggested by Widal and his co-workers. In his discussion (chapter XXII, pp. 228-244) Vaughan gives the technique in minute detail, emphasizing the care required and the many possibilities for error. He also mentions, though briefly, those workers who found the leukopenic index unreliable and of no clinical value (Loveless et al., Brown et al., Hill et al.). His final sentence in this discussion, written in 1939 is as follows: "We must conclude that the leukopenic index is still in the experimental stage and cannot be discussed at this time as a routine diagnostic procedure in allergy." Most allergists would agree that this sentence today in 1944 is a fair summary of the degree of usefulness of the leukopenic index. Fewer allergists make use of it today than six years ago.

SOME AIMS OF AN ANESTHESIOLOGIST

CHAIRMAN'S ADDRESS

PAUL M WOOD, M D
NEW YORK

Full and permanent recognition of the anesthesiologist as a practicing physician depends on the accomplishment of several major aims. Among these are an adequate supply of physicians competent to render complete service in anesthesiology to every patient, establishment of adequate education in this subject in all medical schools, dissemination of accurate information about the specialty, assumption of full responsibility by the anesthesiologist as a physician and the development of economic security for the practitioner.

The armed forces realize the value of the physician in this special practice. They have established special teaching centers where medical officers are being instructed to become the directors and teachers in the larger units.

Is there a place for anesthesiologists in the postwar plan? In 1941, of 5,700 hospitals reporting anesthesia services, only 2,750 had a physician in charge. If all doctors received basic instruction in this field, that situation would not exist.

The American Board of Anesthesiology has certified 233 physicians in the specialty. The American Society of Anesthetists has certified more than 200 of its 1,700 members as Fellows in Anesthesiology. It is self evident that there is an immense postwar opportunity in this field, which is definitely undermanned at present.

Basic teaching of the subject in all approved medical schools must be established. At present there are a few excellent active required junior and senior medical student courses being given. Others are listed but are inactive, and many schools do not provide courses in this subject. In war curriculums few interns receive sufficient clinical experience and still fewer any personally supervised instruction in this specialty. More approved residencies must be established in this field if the major aim of the anesthesiologist is to be realized. In order to obtain the proper educational facilities for this specialty, a genuine demand must be aroused. This can be done by individual and organized efforts to inform the medical, hospital and lay public of the many important and varied services available by the qualified anesthesiologist. Every medical graduate should receive sufficient basic instruction so that he may intelligently deal with problems in anesthesia. Such instruction is

required for all medical students in England and Canada. This would eliminate the necessity of many hospitals having to rely entirely on a limited technical anesthesia service.

For economic reasons hospital managements have been too satisfied with the mere technical service of nonmedical employees. This deprives the patients of many valuable services. The nonmedical anesthetist who may have technical ability cannot practice medicine and thus cannot perform many of the duties of the anesthesiologist. Nominal supervision by a physician the graduate of a medical school giving no instruction in the basic principles of anesthesiology and of an internship giving meager clinical experience is a farce and a subterfuge. The anesthesiologist must be competent to direct, conduct and teach anesthesia in all its forms, including inhalation therapy and resuscitation. He must assume and accept full responsibility and maintain his professional integrity. There must be an intimate personal relationship between patient and anesthesiologist in the interest of safety, efficiency and responsibility.

The assumption of full responsibility and the maintenance of the personal relationship of doctor and patient require a type of remuneration in keeping with the private practice of medicine. The current practice of physician anesthesiologists accepting salaried positions with hospitals tends to impair the personal relationship and divide or remove responsibility. The status of the physician may then be reduced to that of a hospital employee, with loss of prestige, incentive to better work and freedom of action. His judgment may be regulated by economic rather than by medical concepts. Responsibility is of the utmost importance in medical practice. Those who shirk responsibility should not expect to enjoy the privileges, respect or rewards of the medical profession.

It is to be regretted that the federal government, in its effort to secure greater economic benefits for all, did not include this specialty in its postwar planning board. Efforts must be continued to secure proper representation there, so that relocation and logical distribution of qualified anesthesiologists may be assured. With the sociologic trend to greater social security, the status of the specialty has been placed in jeopardy. It is acknowledged that hospital service plans have benefited both the lay public and the physician. Hospital service and medical service are distinct and should so remain.

Organized anesthesiology can assist its members by its postwar planning committees, by establishing fellowships, research facilities, libraries and postgraduate refresher courses. It can establish and develop cooperation with the various educational, medical, surgical and hospital groups. It should be relentless in demand-

Read before the Section on Anesthesiology at the Ninety Fourth Annual Session of the American Medical Association Chicago June 15 1944

ing adequate instruction in anesthesiology for every physician and suitable postgraduate instruction for the specialist. This education must extend from medical student days, through internship and residency. Organized anesthesiology must inform the medical, hospital and lay public that in striving for these aims its final goal is to provide competent, safe and efficient service in anesthesiology for every patient.

DIAGNOSIS OF HERNIATION OF LUMBAR INTERVERTEBRAL DISKS BY NEUROLOGIC SIGNS

J. JAY KEEGAN, MD

OMAHA

A new concept of neurologic manifestations of herniation of lumbar intervertebral disks has been presented in two preceding publications¹ which clarify the clinical interpretation of this condition. The practical application of this knowledge is important in the general practice of medicine and a brief review with additional information is herewith presented.

Since the initial stimulating publication in 1934 by Mixer and Barr,² who demonstrated herniation of intervertebral disk by intraspinal injection of iodized oil and surgical exploration, there have been many contributions to the subject with increasing emphasis on the frequency of the lesion and localization by means of neurologic signs. There remained however, lack of clear definition of the symptoms and signs of single nerve root compression by the common herniation of the nucleus pulposus of a lower lumbar disk. The symptoms caused by this herniation are those which in the past have been called "lumbago" and "sciatica," terms which now are recognized to have little meaning except general location of the pain.

Careful study of the history in cases of proved herniated disk rather constantly elicits the story of preceding episodes of "lame back," with or without a sudden "slip" sensation under stooping lifting strain. These attacks now are recognized to represent beginning softening and loosening of the nucleus pulposus within the disk, with posterior shift and stretch of the enclosing ligament (fig 1). The patient has pain located in the lower lumbar region, usually not lateralized, although he may list to favor one side, and he cannot straighten his back well because of the pain.

Theoretically, this early posterior displacement of the nucleus pulposus within the disk should be replaceable by proper manipulation, as it has not yet herniated in sufficient degree to be fixed in its position. Actually, many of these nucleus pulposus dislocations have been replaced by various maneuvers under the guise of doing something else. The orthopedic surgeons have massaged and manipulated for "strained ligaments and myofascitis," neurologists have "stretched the sciatic nerve" and osteopaths and chiropractors have "replaced dislocated vertebrae" and "released pinched nerves," with some element of success in all measures. The reason for

success in cases of herniated disk has been the occasional accidental replacement of the nucleus pulposus to its normal central position or the subsidence of acute inflammatory swelling and size of the herniation with passage of time.

A general physician, Dr A. W. Abts,³ recently reported to me, half apologetically, that "he was relieving by manipulation the great majority of patients who came to him with very sudden acute disabling low back pain which caused them to assume a trunk-thigh flexion deformity favoring the affected side. Pain is characteristically localized over the lower lumbar area and the symptoms are produced often by very slight provocation, such as stooping to pick up an article from the floor or stooping of any kind. The manipulation is done with the patient lying on his back, both legs extended (fig 2). The first maneuver is to flex the leg acutely on the thigh and the thigh on the abdomen, at first cautiously a few times on the least affected side, then more suddenly and forcibly. The second maneuver is forceful full extension of the leg by combined kick of the patient and pull with the operator's hand on the ankle. This procedure then is repeated on the more affected side, repeating one to ten times as seems needed by report of relief by the patient. This is noted by the ease with which the patient can extend the leg on the table or can be determined more certainly by having the patient stand, when he can walk erect and is able to bend forward without pain. No support is needed for the patient who is treated the same day of the onset of symptoms, and he may resume work. The patient who is treated a few days after the onset has overlapping adhesive tape applied to the lower lumbar region and is advised against his usual activity for three or four days. This manipulation is not original, but the source by reference cannot be found at the present time." This manipulation would first open the posterior disk border, favoring restoration of the nucleus, and the sudden longitudinal jerk would widen the entire disk and tend to suck the partly herniated nucleus back to its normal central position. Other maneuvers might work as well, particularly if muscle relaxation were obtained by anesthesia. But manipulative treatment should be predicated on the assumption that the great majority of these sudden back "slips" with following lameness are posterior displacement of the nucleus pulposus and not other somewhat hypothetical pathologic conditions.

True herniation of the nucleus pulposus occurs when the enclosing annulus is ruptured and sufficient amount of fibrocartilage escapes through the opening beneath the posterior longitudinal ligament to produce an intraspinal tumor and pressure on a nerve root (fig 3). This rupture may occur suddenly or gradually, the distinguishing sign being the appearance of definite unilateral nerve root compression symptoms, usually described by the patient as aching in the "hip" or superior midgluteal region and variable sharper pain radiating down the posterior thigh and calf, so-called "sciatic" pain.

Several factors are involved in this common nerve root compression by an intervertebral disk herniation. The rather constant location of the herniation on the posterior surface of the disk to one side of the midline, directly beneath an emerging nerve root leads to early compression of a single nerve root. In most persons the spinal canal is considerably flattened or narrowed at the lumbosacral junction, which leads to earlier com-

pression here of the nerve root against the overlying ligamentum flavum and lamina. Some persons have a much larger spinal canal than others and may have many episodes of low back trouble without definite nerve root symptoms, as displacement of an unrestricted overlying nerve root is not likely to cause much nerve root pain. The nerve root is fixed laterally as it enters the intervertebral canal, and there is a tendency for the somewhat medial herniation to compress the nerve root in the narrow lateral angle of the spinal canal beneath a special lateral portion of the ligamentum flavum.

This part of the ligamentum flavum deserves a separate description and name, for it is not a part of the true ligamentum flavum between laminae but a deeper very dense ligament extending between the base of articular processes. In surgical exploration for herniation of the fifth lumbar disk (fig 4) this ligament appears as a

Fig. 1—Early herniation of nucleus pulposus of fifth lumbar disk giving rise to low back pain without nerve root radiation

deep lateral longitudinal band after the ligamentum flavum attached to the first sacral lamina has been removed. This deep ligament, with suggested name of "interarticular ligament," must be removed before adequate lateral exposure and decompression of the nerve root and herniation can be obtained.

The first and commonest complaint from nerve root compression by herniation of a lumbar intervertebral disk is pain in the "hip," the patient pressing deeply in the superior midgluteal region over the sacroiliac ligament or hip joint. This common location of pain in low back syndromes has had various interpretations the oldest being sacroiliac strain which now is recognized to occur very rarely. It has been called the superior gluteal nerve syndrome, although this nerve is entirely motor. Late myofascitis of the sacrospinalis and gluteal muscle attachments has been a popular diagnosis, or the piriformis and tensor fasciae latae muscles have been blamed. These rather hypothetical explanations have not been very well proved and have not well explained the later radiation of pain down the leg, for which the assumption of reflex pain or sciatic neuritis had to be added. In view of our present knowledge of the sequence in herniation of an intervertebral disk the most logical explanation for this "hip" or superior midgluteal pain is the first sensory contact of the posterior

primary division of the compressed nerve root against the overlying ligamentum flavum. The sensory distribution of this nerve division is to the gluteal area subjectively involved. The motor portion of the root lies anteriorly against the herniation while the central part of the root is formed by sensory fibers for the anterior primary division to the leg (fig 3).

Fig. 2—Manipulation for reduction of early herniation of the nucleus pulposus of a lower lumbar intervertebral disk (used by Dr. Abts)

Greater compression of the nerve root involves the anterior primary division which joins four other roots to form the great sciatic nerve and supply sensation to the lower extremity (fig 5). It should be emphasized that each of the five roots forming the sciatic nerve represents a segmental sensory and motor distribution which is arranged in serial order as the dermatomes of the trunk. The difficulty in the leg is that this order of distribution is obscured by the extension and rotation of the leg in limb bud development and the fusion of the nerve roots in the sciatic plexus which makes single

Fig. 3—Partial herniation of nucleus pulposus of intervertebral disk with rupture of annulus fibrosus stretch of posterior longitudinal ligament and compression of single nerve root causing low back and nerve root pain

root dissection to areas of skin and muscle impossible. This has led to confusion and a tendency to think and speak in terms of peripheral nerves instead of nerve roots to the extremity.

The great sciatic nerve, supposedly involved in "sciatica" or "sciatic neuritis" supplies sensation to a

large area of the lower extremity which includes the entire foot and most of the leg below the knee (fig 6). It is not likely that a true sciatic neuritis would select only one portion of this nerve and cause pain which is distributed only down the back of the thigh and calf and lateral ankle and foot as is the usual location in so-called

The pin scratch then is passed lightly from this area around the leg or foot until the patient reports by signal a definitely sharper area, which point is marked with ink. By repeating this procedure up and down the lower extremity a definite and constant dermatome pattern will be outlined by the patient, usually corresponding to one root of the dermatome chart presented in figure 7. The patient's almost startled response to increased pain at the border line is striking, even when there may be some question of difference when the pin is stroked independently in the different areas. The border reaction almost seems like hyperalgesia, but passing the pin in the opposite direction from the normal to the hypalgesic zone rarely elicits any increased pain reaction at the transition line. When the patient is asked to describe the difference in sensation in the hypalgesic and normal zones he usually states that, while the pin feels sharp in the hypalgesic zone, it is not disagreeably painful as in the normal zone. This is a fine degree of difference, although very definite to the patient, and necessitates careful control of very light pin point pressure, varying somewhat with thickness of skin and with individual patients who react differently to pain sensation. By this method, in over 80 per cent of cases with unilateral "low back and sciatic" pain suggestive of herniation of an intervertebral disk a characteristic dermatome strip of hypalgesia, in part or in full, can be outlined for one of the lower lumbar or first sacral nerve roots. This is diagnostic of direct single nerve root involvement, regardless of the cause, and is in disagreement with the dictum of Foerster⁵ that "division of a single nerve root produces no loss of sensibility," and with both Foerster's and Head's⁶ charts of the dermatomes of man. Confirmatory findings of continuous segmental innervation in the lower extremity have been noted by Richter and Woodruff, with lumbar sympathetic ganglionectomy and by Inman and Saunders⁸ from the "sclerotomes" in deep tissue pain reaction.

"sciatica" This distribution rather accurately is that of the first sacral nerve root, as proved in 72 cases of operation for herniated fifth lumbar intervertebral disk, reported in previous articles¹ and shown in figure 7 of this paper. The pain of fifth lumbar nerve root involvement, if a careful history is obtained, is found located by the patient more lateral on the thigh and leg, to the front of the ankle and the top of the foot and middle toes. Fourth lumbar nerve root pain is located definitely anterolateral on the thigh, over the knee cap and down the medial tibia to the great toe. Third lumbar root pain is to the anterior thigh and medial knee region. Occasional subjective numb or "asleep" sensation in these patients will be located even more accurately in the single nerve root distribution. Thus it is seen that a careful history alone will give fair indication of the single nerve root involved in compression by herniation of a lumbar intervertebral disk. This fairly reliable segmental distribution of pain has been reported by Kellgren⁴ by injection of interspinous ligaments and from this a dermatome chart drawn.

More accurate nerve root identification can be determined by careful outlining of the nerve root areas of slightly reduced sensation, called dermatome hypalgesia, for each nerve root. This testing is not difficult, it is done by simple light pin scratch or prick which the patient identifies as differing degrees of sharpness, not numbness. First the dermatome area suspected by the pain distribution is tested and compared with the similar area on the other leg and with other areas on the same leg usually best in the calf or on the foot. A report of "not quite so sharp" identifies the hypalgesic area

The nerve root most commonly compressed by a herniation of an intervertebral disk is the first sacral root by the fifth lumbar disk. There is varying opinion as to this frequency, most reports of large series of proved cases placing the figure over 50 per cent. In my series of 243 lumbar dermatome hypalgesia cases 145, or 59.7

per cent, were of first sacral nerve root distribution, 74 of them proved by operation, in comparison to 66 cases, or only 27.1 per cent, of the fifth lum-

bar root, 26 cases, or 107 per cent, of the fourth lumbar root and 5 cases, or 21 per cent, of the third lumbar root, as shown in the table. This great predominance of the first sacral nerve root syndrome is in agreement with the observation both by patients and by physicians that the commonest location of pain called

"sciatic" is down the posterior thigh and calf to the lateral ankle and foot, which accurately describes the first sacral nerve root distribution (fig 7)

Since the first sacral nerve root is so commonly affected in herniation of the fifth lumbar intervertebral disk, it is well to keep in mind some anatomic points of this region, which explain many peculiarities of this involvement (fig 5). The first sacral nerve root is rather long in its extradural course within the spinal canal, measuring 3 to 4 centimeters in length. It leaves the main dural canal above the fifth lumbar disk and courses well lateral in the flattened spinal canal of the first sacral region. The sensory ganglion of the root lies beneath the first sacral lamina below the disk, and hence herniation compresses the nerve root proximal to the sensory ganglion and distal to the motor gan-

Fig 6—Peripheral sensory distribution of the great sciatic and small sciatic nerves in the lower extremity (Gray's Anatomy)

glion cells in the spinal cord. This fact is significant in regeneration of root fibers after root destruction by compression. Motor regeneration may be expected to occur unless an obstructive nerve root fibrosis has developed, but sensory regeneration may not occur, as this interruption is proximal to the ganglion and cannot be guided by nerve sheath after it enters the spinal cord.⁹ An excellent example of this was in a case with large fifth disk herniation which compressed three nerve roots and caused wide sensory loss and foot drop. Eighteen months after the herniation had been removed and the nerve roots decompressed there was complete return of motor function in the foot but only partial recovery of sensation. At operation a completely compressed or dead nerve root can be identified by the absence of motor response in the leg to stimulation by pinching or the faradic current.

Another anatomic peculiarity of nerve root compression by herniation of lumbar disks is the absence of so-called trophic manifestations in the distribution of the root, as occurs when peripheral nerves are subject to chronic irritation. There is no hyperalgesia, no burning sensation, no alteration of circulation or temperature, no disturbance of sweating. It is fairly well established that these phenomena, commonly called trophic or causalgic, are related to sympathetic innervation and can be relieved in considerable degree by sympathectomy.¹⁰

There is no outflow of preganglionic sympathetic fibers in the spinal roots below the second lumbar root level¹¹ (fig 8), hence the common compression of these roots by herniation of lower lumbar intervertebral disks does not affect sympathetic innervation in their distribution. For this reason the diagnostic reduction of electrical conductivity on the skin of interrupted peripheral nerves, which is largely dependent on sympathetic loss of sweating in the area, is not applicable to nerve root lesions from herniation of lumbar intervertebral disks.

The lumbosacral articulation in man is a very variable and poorly constructed region for support of the trunk with heavy lifting strain. The lumbosacral spine is set at a 20 to 80 degree angle on the tilted sacrum, and the fifth lumbar and first sacral vertebrae are subject to common

Distribution of Cases with Dermatome Hypalgesia

Dermatome	No of Cases	Per Cent	Verified by Operation

anatomic defects such as bifid spines and transitional types of vertebrae, with large and at times articulated transverse processes, variably faced articular facets, and occasional defective pedicles of the laminal arch, leading to spondylolisthesis. Because of these many structural variations and weaknesses, much lumbosacral pain has been attributed to them and spine fusion operations done for better stabilization, without careful consideration

the main feature of the complaint, it is necessary to relate the pathologic condition directly to an involved nerve root on that side. This is particularly true when the back pain has disappeared, owing to complete herniation of the nucleus pulposus through the posterior longitudinal ligament, as often occurs in late cases (fig 9). When the first sacral nerve root syndrome appears, with loss of ankle jerk, it is impossible to

root at operation, section of the sensory portion of this nerve root may be warranted to relieve the pain satisfactorily.

Third lumbar nerve root involvement is not often associated with herniated intervertebral disk but is more likely to be involved in the common lateral hypertrophic bone disease of this region, old fracture dislocation interference or metastatic cancer from the prostate.

The second sacral nerve root can be involved over a sixth lumbar disk when there are six well formed lumbar vertebrae, or by wide herniation of other disks which compress medial nerves of the cauda equina. An occasional variation occurs in the position of nerve roots, usually associated with anatomic abnormality in the form or sequence of cervical or thoracic vertebrae which places the sciatic nerve roots one vertebra higher than the rule and hence might place the second sacral nerve root, by dermatome pattern, over the fifth lumbar disk.

The treatment of herniation of an intervertebral disk should be conservative until recurring serious disability or continuing intolerable pain make surgical intervention seem necessary. If the interpretation is correct that most low back and sciatic pain is due to varying stages of intervertebral lumbar disk herniation, few persons escape some episode of this nature and in the past the great majority of them have recovered without disk surgery. However, ultraconservatism should not be practiced when satisfactory progress is not being made after a few weeks of bed rest, traction, cast, brace or belt, or when a clear diagnosis of large complete herniation of the nucleus pulposus can be made (fig 9) based on continuing nerve root pain at rest. With our present knowledge and surgical technique of herniated disk it is possible to relieve this patient immediately of his leg pain and enable him to walk out of the hospital in comfort two weeks or less from the operation, without back support and able to resume work two to six weeks later. There is no great risk to the operation, as the disk herniation can be removed by retraction of the sacrospinalis muscle and removal of the liga-

Fig 8—Diagrammatic representation of sympathetic outflow from the human spinal cord in the lumbosacral region. Note that compression of nerve root by lower lumbar disk herniation does not involve sympathetic fibers to the lower extremity. (Modified from Foerster.)

attribute this to any extraspinal bone pathology, as the first sacral nerve root is entirely intraspinal until it enters the first sacral foramen of the sacrum.

Fifth lumbar nerve root compression commonly is caused by herniation of the fourth lumbar disk, although at times it may be compressed more laterally by a wide herniation of the fifth lumbar disk or hypertrophic bone thickening around an old degenerated and narrowed fifth lumbar disk. The fifth nerve root is not contacted by an enlarged fifth lumbar transverse process. Differential diagnosis of this nerve root involvement is difficult, both because of the several factors involved and because of the greater difficulty in outlining the dermatome hypalgesia of this root, with no characteristic reflex loss.

Fourth lumbar nerve root compression by herniated disk occurs infrequently, found in 10.7 per cent of my series of 243 cases, as shown in the table. It seems to occur more often in an older age group, around 50 years, whereas the first sacral nerve root syndrome is more common in the late thirties and the fifth lumbar nerve root syndrome in the forties, with exceptions in all groups. The fourth lumbar nerve root may become involved in the intervertebral canal from lateral herniation of the fourth disk, where the pathologic condition may be missed at operation. In such a case with the characteristic fourth root syndrome of dermatome pain and hypalgesia, absent knee jerk and failure of the leg muscles to jerk on pinching the fourth lumbar nerve

Fig 9—Complete herniation of nucleus pulposus with rupture of posterior longitudinal ligament. This herniation is not reducible and is diagnosed by disappearance of low back pain and increase of nerve root pain at rest.

mentum flavum on only one side of the spine (fig 4). Usually some bordering lamina is removed for better exposure and adequate decompression of the nerve root. This does not significantly alter the supporting structure of the back, in fact, the scar tissue of healing may serve for better fixation of an unstable back. The main part of the disk or annulus remains in place. However, a person, usually in his late thirties who

has developed herniation of a lumbar intervertebral disk should recognize that he has reached middle age and should always protect his back from heavy stooping lifting strain. This advice applies whether he has developed herniated disk or not. The operation should not be expected to give rejuvenation or restore a pathologic disk to normal.

SUMMARY

The terms "lumbago" and "sciatica" have little meaning except to indicate the general location of pain.

The early stage of lumbar intervertebral disk herniation is not distinguishable from other pathologic conditions supposed to cause low back pain.

Posterior displacement or partial herniation of the nucleus pulposus within the disk often is reducible by manipulation.

More extensive herniation of the nucleus pulposus is not reducible and causes unilateral pressure on a nerve root within the spinal canal, with pain radiating in that nerve root distribution.

The nerve root is compressed beneath a special lateral portion of the ligamentum flavum (interarticular ligament?).

The most constant location of nerve root pain in the "hip" or midgluteal region is explained by the first sensory contact of the posterior primary division of the root against the ligamentum flavum.

The pain of true "sciatic neuritis" should be located in the entire distribution of the great sciatic nerve and not limited to the posterior thigh and calf and lateral ankle and foot. This common location of so-called "sciatic" pain represents first sacral nerve root distribution.

The location of pain of fifth, fourth or third lumbar nerve root compression can be distinguished from first sacral nerve root pain if a careful history is obtained.

More accurate identification of nerve root involvement can be obtained by careful outlining of areas of slightly reduced pain sensation or dermatome hypalgesia.

Recognition of the commonest first sacral nerve root syndrome with herniation of the fifth lumbar intervertebral disk removes most other pathologic findings as a possible cause of this syndrome.

Motor regeneration of compressed intraspinal nerve roots would be expected to occur more completely than sensory regeneration because of the location of the compression proximal to the sensory ganglion.

The absence of trophic or sympathetic phenomena with lower lumbar nerve root compression is explained by the absence of sympathetic fibers in these roots below the second lumbar root level in man.

Signs of organic loss of nerve root function, by the finding of sensory or reflex loss, necessitates the location of causative pathologic changes directly on that nerve root and does not permit the interpretation of reflex pain from some distant region.

Treatment of herniation of an intervertebral disk should be conservative until seriously disabling and persisting or recurring pain gives indication that a fixed herniation is present.

The operation for herniation of a lumbar intervertebral disk is comparatively safe and does not weaken the supporting structure or function of the back.

Relief by operation should not be postponed an unreasonable length of time for the nerve root pain is immediately relieved and the patient able to be back on his feet in comfort in less than two weeks.

PHYSICAL FITNESS TESTS FOR CONVALESCENTS

PETER V. KARPOVICH, M.D.

RANDOLPH FIELD, TEXAS

LIEUTENANT COLONEL MERRITT P. STARR

MEDICAL CORPS, ARMY OF THE UNITED STATES

AND

CAPTAIN RAYMOND A. WEISS

AIR CORPS, ARMY OF THE UNITED STATES

The Air Surgeon directed the activation of a convalescent training program for patients in Army Air Forces hospitals in December 1942.¹ The general objective was to use the hospital days of every clinically available patient for military education and for complete physical rehabilitation, so that on discharge the soldier would have additional training and be prepared physically for full military activity without danger of relapse and without any substandard duty. The hospitalization required by his illness would thus become also a physical and mental educational period. The introduction of physical training in the convalescent training program of the Army Air Forces hospitals produced a revolutionary change in the management of patients.² Whereas heretofore the convalescents merely vegetated in idleness, efforts are now made to maintain and even increase the degree of their physical fitness. Practical questions soon arose. When was it safe and beneficial for patients hospitalized for acute infectious diseases to take part in the physical training program and when were they ready for discharge from the hospital to full activity? To answer these questions the present study was undertaken. It was conducted between Jan 10 and May 15, 1944 on 417 aviation cadets and students who were patients of the Medical Service in the AAF Regional Hospital, San Antonio Aviation Cadet Center, recovering from primary atypical pneumonia, influenza, nasopharyngitis, tonsillitis and other upper respiratory infections.

CLINICAL PHYSICAL FITNESS TESTS

Since the convalescent physical training program is divided into ward and outdoor programs, it was considered desirable to devise three tests for (1) participation in the ward program, (2) participation in the outdoor program and (3) discharge from the hospital to active duty. These tests were to be used by the medical officer, in much the same way as laboratory tests, to aid him in deciding when the patient is fit to participate in the ward and outdoor physical training programs and when he is fit for full military duty. Physical training for convalescents is divided into three programs: red, blue and green. This is done in order to insure gradual progression in the intensity of exercise and the amount of work done.

(a) The red program consists of mild calisthenics given in the ward for ten minutes twice a day.

(b) The blue program consists of calisthenics, games and a moderate amount of running, combatives and guerrilla.

From the Laboratory of Physical Fitness, AAF School of Aviation Medicine, Randolph Field, Texas (Dr. Karpovich and Captain Weiss).

Lieutenant Colonel Starr is Chief of Medical Service, AAF Regional Hospital, San Antonio Aviation Cadet Center, San Antonio, Texas.

Assistance in conducting this investigation was given by Lieut. Edwin C. Womble, M.C., and Private Mary J. Talaska of the AAF Regional Hospital, San Antonio Aviation Cadet Center, San Antonio, Texas.

exercises. It is scheduled outdoors twice daily, one period being thirty minutes and the other forty-five minutes.

(c) The green program includes all the activities of the blue one, to which wind sprints and cross country running are added. It is given twice daily, each period being forty-five minutes.

This daily exercise program is the active factor in conditioning the patient for return to duty. The physical fitness tests determine the progress of the patient toward this goal.

The tests used in the present study were called the red test, the progressive test and the discharge test. During the first part of this study the red and progressive tests were given by members of the investigating staff, but later these tests were administered by the nurses in their respective wards. The nurses learned the technic of the tests quickly and conducted them efficiently. The time consumed did not interfere with their other duties. The discharge test was given by the physical training instructors assigned to the convalescent training program.

The Red Test—The red test was used to determine when the patients could participate in the red program. In the construction of this test the simplest possible form was used. The test consisted in stepping up and

Chart 1—Pulse rate one minute after red test

down³ as in the Harvard step-up test⁴ on a 20 inch box, twelve times in thirty seconds. The sitting pulse rate was taken for thirty seconds, beginning one minute after exercise. Pulse rates of less than 100 per minute were considered passing. After a patient passed the red test he was automatically placed on the red program. If he failed, he was retested on succeeding days until he either passed or was finally placed on the red program without passing, if the ward officer felt that the patient would not be harmed by additional physical activity.

In devising the red test, three factors were considered: (1) rise in metabolism, (2) change in pulse rate and (3) degree of muscular coordination. Although it is logical to suppose that the reserve of physical endurance of a hospitalized patient is lowered yet during the testing it soon became obvious that the reserve

was greater than the demand imposed by the red test. This supposition was substantiated on numerous occasions when patients passed a five minute step-up test on the same day or the day after the red test was passed. However, the work accomplished during the red test is approximately equivalent to work done in brisk walking up to the third story of an ordinary building and down again in thirty seconds. It is hard to believe that many medical men would be willing to give more intensive exercise to patients who have just passed the acute stage of illness. As a matter of fact, at the beginning of this study suggestions were made to use only five steps, a decision was made on ten steps, the number was later extended to twelve.

In determining the intensity of the red test, the relation between the comparative rates of metabolism during the planned exercises and the proposed test was considered. Although the oxygen consumption during the exercises of the red program was not actually measured, an estimate of the rate of metabolism was made on the basis of research done by other investigators. According to Kennedy⁵ the metabolism of all exercises given to the British army varies from five to six and one-half times the basal rate, Missiuro and Perlberg⁶ found that the increase in metabolism during Scandinavian gymnastics is four and one-half times the basal. The ward exercises used in the red program are between the British and Scandinavian in intensity. Laboratory determinations showed that the red test increases the metabolic rate eight to ten times over the basal. For this reason it was considered that exercises of lower intensity, such as those in the red program, could be indulged in for even a longer duration, especially since the patient could slow down or stop if he found the exercise too severe for him. Therefore it seemed unnecessary to have a more strenuous test to determine when a patient could enter this program.

In order to establish a criterion for the evaluation of the heart rate reaction, the red test was given to 98 normal aviation cadets from the preflight school and to 78 patients convalescing from primary atypical pneumonia. The frequency distributions of pulse rates one minute after exercise for both groups are given in chart 1.

The curve for the convalescents (chart 1) shows a pronounced shift to the right. Analysis of both curves shows that, if the pulse rate of 94 is taken as the criterion for passing, then 32 per cent of all patients convalescent from primary atypical pneumonia fail to pass the test. Experiments with patients who had a pulse reaction of 96 and 98 showed that they could take ward exercises as easily as the other patients with lower pulse reactions. For this reason, and in order to reduce the possible number of normal people falling into the "pathologic" group, pulse rates of less than 100 per minute were considered passing. By doing so, the number of normal cadets who would have fallen into the "pathologic" group was reduced to 3 per cent.

Stepping in cadence on a box 20 inches in height requires definite muscular coordination. It was observed that patients who had remained in bed continuously for several weeks could not maintain the cadence. Their movements were uncoordinated and their legs were shaky. This lack of coordination in

³ The subject stands in front of the bench and steps up on it with one foot and then the other then stepping down in the same order he must lead with the same foot on each step.

itself, regardless of the pulse reaction, was sufficient indication that the red test was too strenuous for these patients

Progressive Test—The day after the patient passed the red test, with the consent of the ward officer he was given a more strenuous step-up test, called the progressive test, which was used to determine whether a

TABLE 1—Scoring Table for Progressive Test
Convalescent Training Program

Duration of Exercise	Pulse Rate One Minute After Exercise	Physical Training Classification
Below 2 minutes	Regardless of pulse rate	Red
2 minutes to 2 minutes 29 seconds	Below 100	Blue
	Above 100	Red
2 minutes 30 seconds to 3 minutes 29 seconds	Below 110	Blue
	Above 110	Red
3 minutes to 3 minutes 29 seconds	Below 100	Green
	100 to 140	Blue
	Above 140	Red
3 minutes 30 seconds to 3 minutes 59 seconds	Below 110	Green
	110 to 170	Blue
	Above 170	Red
4 minutes to 4 minutes 29 seconds	Below 130	Green
	Above 130	Blue
4 minutes 30 seconds to 4 minutes 59 seconds	Below 140	Green
	Above 140	Blue
5 minutes	Below 150	Green
	Above 150	Blue

patient was qualified to participate in either the blue or the green program. This test is essentially the Harvard step-up test except that the rate of stepping up is reduced from 30 steps per minute to a slower rate because it was observed that some patients were unable to maintain the faster rate. The test consisted in stepping up on the same 20 inch box and down again at the rate of 24 steps per minute and was continued to the limit of the patient's endurance, but not to exceed five minutes. The sitting pulse rate was taken for a period of thirty seconds beginning one minute after exercise. If, during exercise, the patient showed pronounced symptoms of fatigue he was stopped by the nurse and the pulse rate was taken as usual. By way of comparison this test, when completed, required ten times as much work as the red test and is equivalent to walking up to the twenty-first floor of a skyscraper (allowing ten feet per floor) and down again in five minutes.

An attempt was made to assign patients to the blue or green physical training programs on the basis of this test. The following criteria were used: (1) duration of the exercise, (2) pulse rate one minute after exercise, (3) muscular coordination of the patient during stepping up and (4) amount of dyspnea.

The progressive test was given to 100 normal aviation cadets and it was observed that pulse responses resembled those obtained in the Harvard step-up test. For this reason the modified Harvard scoring table (table 1), based on pulse response and duration of exercise, was used in scoring this test also. In accordance with the score made by the patient he remained on the red program or was moved either to the blue or to the green program (table 1). Only 15 out of 250 patients tested did not graduate into the green program the first time they took the progressive test. These 15 were placed in the blue group and passed into the green group within one or two days.

According to the plan of the investigation the progressive test was to be given the day after the red test. However, on some occasions it was given either on the same day or several days after the red test. Results indicate that within five days after passing the red test 83 per cent of the patients passed into the green

test and 92 per cent passed into either the blue or the green physical training programs. These figures should not be interpreted as an indication of the maximum percentage of the patients who could have passed the test because not all of them were tested on these days either because of administrative lag or because the ward officers did not think the patients were ready to be tested. The fact that so few men failed to enter the green physical training program even when it was taken as early as the second day after the red test was passed suggests that the amount of work done in the red test could have been increased and that fears regarding the possible harmful effect of the present red test were unfounded.

Discharge Test—Before this investigation started the Medical Service of the hospital was using the regular Harvard step-up test³ to determine when patients were physically fit to be discharged from the hospital to full military duty. Patients who received a score of 75 or more were discharged. Those who made lower scores were kept on the green program until they could pass the test.

Although the Harvard test has a low correlation with the AAF Physical Fitness test⁷ it was used for the reason of expediency. The weather during the period of investigation was unsettled and it was impossible to schedule the shuttle run required in the AAF Physical Fitness test. However, a follow-up of 271 patients discharged with the Harvard score of 75 was made by the physical director of the hospital and it was found that none of the patients relapsed and that they were able to carry on full military training involving strenuous physical exertion.

Results—An attempt was made to find the relationship between the duration of fever, the time of entering the red and green programs and passing the Harvard test, and the length of hospitalization. For this purpose the data on patients convalescing from primary atypical pneumonia are presented in chart 2.

Chart 2—Study of primary atypical pneumonia

Each number on the abscissa represents a patient. Cases are arranged according to the length of hospitalization. Only patients who took all tests are included. This chart shows that there is no relationship between the duration of fever and the length of hospitalization. It also reveals that the earlier the patient was given the

7 The AAF Physical Fitness test consists of sit ups, pull ups and a 300 yard shuttle run.

red test, the earlier he was able to enter the green physical training program (see the solid area, chart 2). Yet on many occasions the Harvard test was delayed for a number of days because, in the opinion of the ward officer, the patient was not ready for the test. This indicates a discrepancy between the clinical opinion and the actual physical fitness of the patient as revealed by the test. These statements regarding pneumonia cases are applicable to patients convalescing from the other diseases mentioned in this report (table 2).

Some of the medical officers thought that testing and exercising might increase the sedimentation rate and as a result, cause a relapse, or that the lung conditions in the case of respiratory diseases might be aggravated. It is outside the scope of this study to investigate this

TABLE 2—Statistical Data on Progress in Convalescence in Various Diseases

	Primary Atypical Pneu- monia Mean	Naso- pharyn- gitis Mean	Influ- enza Mean	Upper Respir- atory Infection Mean	Tonsil- litis Mean

relation in detail, but evidence has been obtained to question the basis of this fear.

Examination of table 3 shows that patients with high sedimentation rate successfully not only passed the red test but went on to qualify for the green program and pass the Harvard test. As may be observed from the figures in the "Discharge" column the length of hospitalization for these patients compares favorably with the length of hospitalization for all patients for each disease (table 3). This should not be considered proof that physical exercises must begin regardless of the sedimentation rate. It merely shows that patients with high sedimentation rates can be given exercise without unduly prolonging hospitalization. Further investigation regarding the sedimentation rate is in process and the results will be presented in a separate report.

COMMENT

A highly debatable topic is the relationship between x-ray findings of the lungs in the case of primary atypical pneumonia and the time for starting physical exer-

cises. The opinions of the medical officers who were contacted during this investigation varied but the majority seemed to be against "early" exercises. The interpretation of the word "early" also varies a great deal. In the present study neither testing nor participation in the physical training program, notwithstanding positive x-ray findings, caused aggravation of symptoms or subsequent lengthening of hospitalization of the primary atypical pneumonia cases. However, chart 2 shows that there are long intervals of time in some cases between entering the green program and passing the Harvard test. This was usually due to the fear of the medical officer that the Harvard test would be harmful to the patient.

Hyperventilation of the lungs has been recognized as a therapeutic measure for lung atelectasis, and for this reason respiratory gymnastics of various kinds have been suggested. The desired amount of lung ventilation may easily be obtained by means of ward exercises of the proper intensity. This method may have an additional advantage over mere hyperventilation because the blood circulation through the lungs is also augmented.

It should be stated here that by the very nature of this study it was impossible to adhere strictly to a rigid plan. On many occasions the records are incomplete because some of the tests were omitted. The main reason for this was a deep rooted belief in the curative power of rest and a fear of early participation in physical exercises by convalescing patients on the part of both investigators and medical officers. However, with the progress of the present investigation this fear was reduced to a great extent and an earlier assignment of the patients to tests and physical training resulted. Before the present testing program was introduced at the San Antonio Aviation Cadet Center AAF Regional Hospital the average number of days of hospitalization of primary atypical pneumonia patients was 23.25. After the introduction of the testing the average dropped to 17.4 days. This difference is statistically significant, the critical ratio of the difference is 4.57. The objection may be raised that these patients belonged to two different calendar periods. The first group was hospitalized before Jan. 10, 1944 and the second after that date, therefore the virulence of the disease might have been different. It is the opinion of the investigators that improvement was not due solely to calendar difference, because it was observed that the earlier a patient was tested the sooner he was discharged from the hospital.

It is important to remember two factors in applying the results of this investigation. (1) The types of disease studied were of an acute nature and of comparatively short duration, (2) the patients, aviation students and cadets, represent a selected group possessing a high degree of physical fitness. For these reasons the results should be applied with caution to other personnel and to patients convalescing from other types of diseases. It is the opinion of all persons concerned with the active part of the investigation that no wholesale testing for admission to the red program is necessary. Patients recovering from diseases studied in this investigation may be safely placed on ward exercise on the second day of afebrility and then two days later may be placed on the blue or green program. In cases in which the medical officer is in doubt the red and progressive tests should be given to the patient, preferably in the presence of the medical officer.

The ward physical training program should be mild and the outdoor program should have sufficient gradation. With these conditions patients can safely take the whole physical training program. Occasionally muscle soreness may be encountered but this should not be considered as an indication that the program is too severe.

It was observed that men with a high degree of physical fitness retain a high level throughout the disease. This observation supports the emphasis placed by the Army Air Forces on the importance of physical training for its personnel.

For enlisted men in duties not requiring a high degree of physical fitness, the physical fitness tests used in this study should be adjusted accordingly. The discharge test score of 75 and the five minute exercise limit may be too high.

During the present investigation an attempt was made to test the physical fitness of the patients by allowing them to use their own cadence and even rest when they wished. The total time allowed (including rest periods) was five minutes. The number of steps represented the score.

This type of testing was based on the desire to avoid too much "drive" on the part of the patient. It was observed that patients rapidly improved in willingness to perform step ups and were ready to take the Harvard test. This method of testing was discontinued because of the difficulty in standardization but may be useful in dealing with weak patients who need special care and should avoid strain.

CONCLUSIONS

1 From an analysis of table 2 it is found that three days after an acute fever of two and a half days' duration an AAF cadet can pass a physical fitness test equivalent to walking up to a height of 20 feet and down again in thirty seconds (approximately to the third floor of an average building).

2 One and a half additional days after fever, the convalescent cadet can pass a physical fitness test equivalent to climbing up 200 feet and coming down in five minutes (approximately to the twenty-first floor).

3 After three more days he can make a score of 75 on the Harvard test for discharge to full military duty.

4 The use of the Harvard test score of 75 is reliable for discharge to full duty, since all of 271 cadets were able to carry on without relapse.

5 Testing and participation in the physical training of the convalescent training program reduced hospitalization somewhat, definitely did not prolong illness and insured adequate physical fitness for return to full military duty.

6 From a small number of cases, results suggest (table 3) that sedimentation rate (Westergren method) of the order of 24 to 55 mm is not a contraindication to full participation in the hospital physical training program.

SUMMARY

The clinical physical tests described were used to assist medical officers in classifying AAF cadets convalescing from acute, uncomplicated upper respiratory diseases for participation in a graded physical training program. Participation in the physical training program resulted in a sufficiently high degree of physical fitness for the return of the subjects directly to full military duty when discharged from the hospital.

THE VALUE OF PERIODIC PELVIC EXAMINATION

IN THE CONTROL OF CANCER OF THE UTERUS

CATHARINE MACFARLANE, M.D.

MARGARET C. STURGIS, M.D.

— AND —

FAITH S. FETTERMAN, M.D.

PHILADELPHIA

One of the most important tasks confronting the medical profession today is to find cancer in an early and curable stage. Two methods are available. One is the method of educating the public with reference to the signs and symptoms of early cancer. The other is the method of periodic examination. The latter method is being tested in the Department of Gynecology of the Woman's Medical College of Pennsylvania.

In the spring of 1938 we undertook to determine the value of periodic pelvic examination in the detection of cancer of the cervix in an early and curable stage and in the detection of inflammatory lesions of the cervix which may predispose to cancer.

By means of appeals to our patients to women's clubs, to nurses' auxiliaries, to social service agencies and to the public at large through the press, 1,319 volunteers were found. These were white women between 30 and 80 years of age. They were married or single, with or without children. They came from every walk of life. They were presumably well. They volunteered to come for examination twice a year for five years as a contribution to medical science.

Each volunteer was given a circular to be submitted to her family doctor. In this circular the purpose of the research was described. It contained statements to the effect that the examining physicians were volunteering their services and that if anything abnormal was discovered a report would be made to the family physician with recommendations for treatment. The cooperation of the family physicians has been most gratifying. As a rule they concurred in our recommendations. Sometimes they did not. Sometimes they asked us to carry out the treatment recommended. Sometimes they referred their patients to gynecologists of their choice. In either event we received a report on the treatment given and the nature of the pathologic changes found.

Record cards were filled in for each volunteer. These contained details of menstrual and marital history and of cancer heredity, if any. A family history of cancer was given by 42 per cent of the volunteers.

Only one serious objection was raised against the plan—namely, the possibility of developing or increasing a cancerphobia. Our experience has shown this objection to be unwarranted. Individual volunteers have repeatedly stated that instead of developing a fear of cancer the examinations have given them a "great sense of security."

Financial support for supplies, secretarial service and the salary of a research worker was furnished by generous grants from the Committee on Scientific Research of the American Medical Association, from the Pennsylvania Division of the Women's Field Army of the American Society for the Control of Cancer,

From the Department of Gynecology, Woman's Medical College of Pennsylvania.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

from the New York Medical Women's Association and from the International Cancer Research Foundation

The examination was intentionally kept so simple that it could be duplicated by any physician at any cross-roads of this country. It consisted of a careful bimanual examination and a careful inspection of the cervix in a good light.

In the first 2,000 examinations we used the Schiller test (Lugol's solution applied to the vaginal portion

of the cervix.) Eventually we gave this up, for we found it just as easy to detect diseased tissue without Lugol's solution as with it. Chrobak's test for friability of tissue was found useful in testing areas of papillary erosion. If the blunt tipped pocket probe pressed gently against the area slid off, we felt pretty sure we were dealing with a benign lesion. If the probe sank in, as it would into butter, a suspicion of malignancy was aroused. At first we performed quite a few biopsies. Later we preferred to recommend excision of the entire eroded area. By this means all of the diseased tissue could be sent to the pathologist and the cervix was restored to a healthy condition.

Up to May 15, 1944 a total of 9,111 pelvic examinations had been made. Some 416 volunteers had come regularly twice a year for five years, while some 545 volunteers had more or less intermittently completed the five year period. Since January 1942 the breasts have been examined also.

In the course of these 9,111 examinations, eighteen cancers of ten different organs were discovered by us or reported to us. Table 2 shows how these are classified.

In the first examination of the 1,319 volunteers early cancer of the cervix was discovered three times. The details of these cases are as follows:

CASE 1 (volunteer 430)—C. L., single, aged 39, had had one child born spontaneously. She gave no history of cancer heredity. She consulted us in April 1938 on account of right upper quadrant pain. Since we were busily engaged in finding 1,000 women for our research, a pelvic examination was suggested. This revealed a myomatous uterus reaching three

fingerbreadths above the symphysis and a hypertrophied and badly lacerated cervix. The laceration extended to the vaginal vault on the left side. The vaginal surface of the cervix felt coarsely granular. It bled at several points. At one point there was a yellow slough. A blunt tipped probe sank in at the left corner of the external os. Tissue was taken from this area for biopsy. Dr. Geiss of the department of pathology reported "early squamous cell carcinoma."

On April 7, 1938 the patient was given 2,400 mg. hours of radium in the uterine cavity. On April 28 she was given 2,400 mg. hours against the vaginal cervix. Examination in May 1944 showed no signs of recurrence. Volunteer 430 represents thus a six year cure.

CASE 2 (volunteer 174)—Mrs. M., aged 41, came in response to an appeal to a woman's club. She had had one child born spontaneously. Her maternal grandmother had been operated on for cancer of the breast at 75 and had lived to be 85. At the patient's first examination on April 1, 1939 a bilateral laceration of the cervix was found with an extensive area of papillary erosion. This was reported to her family physician who referred her back to us for treatment. One month later she entered the Hospital of the Woman's Medical College. At this time a violently red tuft of papillary tissue was discovered close to the external os. This was about 2 mm. in diameter and about 3 mm. high. It had not been present at the first examination.

The uterus was curetted and the eroded area was removed by a Sturmdorf trachelectomy. Dr. Geiss reported "chronic cervicitis, papillary erosion, early squamous cell carcinoma." The patient was immediately given 1,500 mg. hours of radium in the cervical canal. This was followed by 2,400 mg. hours against the cervix. Examination on May 12, 1944 showed no recurrence. Volunteer 174 thus represents a five year cure.

CASE 3 (volunteer 68)—Mrs. D., aged 34, had had one child born instrumentally. She was brought by her sister, who was a member of our research group. Her family history was negative for carcinoma. Examination on April 29, 1939 showed a bilateral laceration of the cervix with eversion and an extensive area of papillary erosion.

On May 8 a curettage and Sturmdorf trachelectomy were performed in the Hospital of the Woman's Medical College. Dr. Geiss reported that two sections from one corner of the specimen showed squamous cell carcinoma "comparatively early."

On May 15, 1939 2,400 mg. hours of radium was given against the cervix. On June 19 the patient was given 1,650 mg. hours of radium within the uterine cavity. Examination on May 17, 1944 showed no recurrence. Volunteer 68 thus represents a five year cure.

The fact that these three early cancers of the cervix were discovered in areas of papillary erosion and not in healthy, noninflammatory cervixes is significant. It lends support to the theory that cancer tends to develop in these so-called "areas of epithelial restlessness." For this reason we consider the discovery and cure of such lesions to be an important factor in the control of cancer of the uterus.

CASE 4—A fourth early cancer of the cervix was discovered on the eleventh visit of volunteer 527. Mrs. T., aged 65, had had one instrumental delivery and two miscarriages. She gave no history of cancer heredity. At 45 years of age she had had an application of radium for menopausal bleeding. She joined the research group in April 1938 and came regularly twice a year with negative pelvic findings. At her tenth visit in September 1942 she reported a spot of blood on her clothing on one occasion. The smooth atrophic cervix appeared congested and bled a little on bimanual examination. The patient's blood pressure was 210. In the absence of any demonstrable pathologic condition the spot of blood was considered to be due to arteriosclerotic bleeding and the patient was told to return if it happened again.

Five months later, at her eleventh visit in February 1942 she reported no bleeding and no discharge but examination

revealed a smooth red polypoid growth 1 cm in diameter projecting through the external os. This bled on touch. A biopsy showed adenocarcinoma. Radium needles were inserted into the polypoid growth for 1,300 mg hours, and 2,400 mg hours was given in the uterine cavity. Examination on May 3, 1944 showed no recurrence. Volunteer 527 represents a fifteen month cure.

A cancer of the body of the uterus was discovered in volunteer 1140. Mrs. B., a widow aged 65, had been coming to Dr. Fetterman for pelvic examination twice a year for a long time. She was put on the research list. In April 1938 she reported vaginal bleeding. On April 22 a diagnostic curettage was performed. This showed adenocarcinoma. As she was medically handicapped, surgery could not be considered. The patient was given 2,400 mg hours of radium in the uterine cavity followed by 3,000 roentgens. Examination on May 18, 1944 showed no recurrence. Volunteer 1140 represents a six year cure.

Another cancer of the body of the uterus was reported on the seventh visit of volunteer 898, who had what we considered to be a symptomless myoma not requiring treatment. However, following other advice, she had this myomatous uterus removed in March 1942 by supravaginal hysterectomy in an excellent suburban hospital. Their well qualified pathologist reported a small area of adenocarcinoma in the endometrium just

above the line of removal. We watch this patient with peculiar interest. At her last visit in January 1944 she gave no evidence of recurrence.

A cystic tumor of the ovary was discovered on the tenth visit of volunteer 176, nothing having been detected six months previously. Operation showed this to be a rapidly growing malignant tumor of the ovary with extension to the pelvic peritoneum. Recurrence was prompt. The course is steadily down hill.

Since January 1942 cancer of the breast was discovered three times on the fourth visit of volunteer 257 and on the seventh visit of volunteer 947 and volunteer 1239. These cases were treated by radical mastectomy.

In addition to the pelvic cancers, a variety of benign lesions of the pelvis were discovered. These are classified as in table 3.

The inflammatory lesions of the cervix varied from a mild endocervicitis to areas of papillary erosion the size of a 50 cent piece (30 mm) or larger.

The relation between childbearing and cervical erosions in the volunteer group was investigated by Dr. Eleanor Scott Mary Putnam Jacoby fellow in the Department of Gynecology of the Woman's Medical College of Pennsylvania for 1940-1941. She found the incidence of erosions in the parous volunteers to be 28 per cent while in the nulliparous volunteers it was 14 per cent.

In 295 of the inflammatory lesions treatment seemed necessary and was advised. Treatment was carried out in 200 cases. Our preference was for the Sturmdorf trachelectomy. This operation makes it possible to send an intact specimen to the pathologist and our

experience was less apt to be followed by recurrence than cauterization or conization. None of the treated cases have been put to the test of labor.

The completion of the five year period for which the research was undertaken finds the examining physicians and the major portion of the volunteer group thoroughly convinced of the value of this procedure. The record of five early cancers of the uterus discovered

and cured is certainly gratifying. The elimination of 200 precancerous lesions of the cervix is equally gratifying. The opportunity to see a large number of healthy cervixes has taught the examining physicians to pay more attention to minor deviations from the normal. The education of the volunteers as to the possible significance of certain apparently trifling symptoms has been important. Both volunteers and examiners are ready for "another five year plan."

SUMMARY

A group of presumably well women between 30 and 80 years of age volunteered to come for pelvic examination twice a year for five years to test the value of periodic pelvic examination in the control of cancer of the uterus. A total of 9,111 examinations have been made. 545 volunteers have completed the five year period.

In the course of these 9,111 examinations four early cancers of the cervix and one early cancer of the uterus were discovered. The patients were adequately treated. They remain well, 2 for six years, 2 for five years and 1 for fifteen months after treatment.

Also in the course of the 9,111 examinations, 461 inflammatory lesions of the cervix were discovered. Two hundred of these have been treated and eliminated.

CONCLUSIONS

Cancer of the uterine cervix can be detected in an early and curable stage by means of the periodic pelvic examination of presumably well women.

Inflammatory lesions of the cervix, which may predispose to cancer, can be detected in about 35 per cent of presumably well women by means of periodic pelvic examination.

The death rate from cancer of the uterus could be materially reduced by the semiannual pelvic examination of married women 30 years of age and over.

ABSTRACT OF DISCUSSION

DR NORMAN TREVES, New York There is a potential number of slightly over 26 million women to whom the appeal for cancer prevention might be directed. They should become the potential "volunteers" in cancer prevention clinics. Dr Macfarlane and her associates have discovered 18 malignant lesions in 10 different organs during the course of 9,111 examinations. This is about 0.002 per cent. At first glance one would think this figure excessively small, but if the 26 million women over 20 years of age could be examined for the first time one might expect the discovery of as many as 52,278 malignant neoplasms. This would probably represent cases detected early enough to give a high percentage cure rate. Cancer of the cervix, the most common cancer occurring in females, is the most curable if encountered early. Dr Macfarlane and her associates have given up the Schiller test. This procedure now has apparently outlived its usefulness. It was valuable at the time it was instituted, for it called attention to early malignant lesions of the cervix, especially those which our pathologists often report to us as "intraepithelial carcinoma." The educational significance of periodic examinations for apparently trifling symptoms has been well worth while. I am sure that it has given all of the "volunteers" in this cancer prevention clinic a sense of security which they otherwise would not have had. With over 164,000 deaths from cancer in the United States and with probably over half a million patients alive with various malignant conditions, education of both the public and the profession must go speedily forward. The ultimate goal of cancer prevention clinics is to influence individuals to accept periodic cancer health examinations as the best means of reducing the mortality in cancer and allied lesions and many other types of chronic disease. Uterine cancer is so accessible that here at least is an approach to cancer control which requires only fingers to feel and eyes to see. It demands no unusual skill, no special instruments. A gloved hand, a speculum, forceps and good illumination are practically the only essentials for competent examination.

DR AUGUSTA WEBSTER, Chicago A clinic was started at the Women's and Children's Hospital in Chicago under the auspices of the Women's Field Army of the American Society for the Control of Cancer in May of last year. The object of the clinic was to examine persons without symptoms or with mild symptoms, with the intent to discover any evidence of early cancer. Detection alone of suggestive lesions was the objective and biopsies and treatment were left to the patient's private physician. The scope of the Chicago venture has been enlarged to include a general physical examination and routine laboratory procedures, such as urinalysis, blood count and the Wassermann test. The emphasis is therefore placed on general health conservation as well as on detection of early cancer. Many constitutional diseases have been found in the course of our work and a number of lesions have been found which are suggestive of early cancer. All the patients have been referred to their private physicians for treatment. In the first 400 cases we found 5 carcinomas of the breast, 2 carcinomas of the breast axillary, 1 basal cell carcinoma of the scalp, 1 basal cell carcinoma of the face, 1 adenocarcinoma of the fundus and 2 advanced inoperable pelvic cancers. We also found the following possible malignant growths: 2 breast masses, 3 friable polyps, 5 skin lesions, 1 suggestive lesion of the tongue, 1 postmenopausal bleeding, 1 suggestive (ovarian?) mass, 1 case of suggestive gastric symptom and 1 lymphatic leukemia. Such work as described by Dr Macfarlane accomplishes much in the way of health education and health conservation. Many of the discouraging hopelessly late cancers could be avoided if the patients would present themselves for examination at regular intervals and if the doctors would look carefully for early signs and symptoms of cancer.

DR CATHARINE MACFARLANE, Philadelphia I should like to emphasize the importance of the six months interval. When we started on this research we had no idea how often these patients should be examined, but the fact that 1 cancer of the ovary developed in a six months interval, 1 cancer of the cervix developed in a six months interval and since this paper was completed a sarcoma of the endometrium has developed in a six months interval after previous normal examination seems to prove the point that the six months interval is not too short.

DIAGNOSIS OF ORBITAL TUMORS

ADDRESS OF THE GUEST OF HONOR

WILLIAM L. BENEDICT, M.D.

ROCHESTER, MINN.

Every case of orbital tumor presents a problem in diagnosis. Features concerning the onset and course of signs and symptoms of tumor are the factors which when put together, constitute the basis for distinction from diseases of the orbit that simulate tumor. These factors are open to various interpretations for the significance of any one of them must be regarded in the light of all other factors that can be ascertained. Certain signs are present in some degree in progressive stages of growth of all orbital tumors. For the most part they are anatomic and result from changes of situation and size of the tumor with displacement of the globe and orbital contents. As all orbital tumors are space-taking lesions, the displacement of the eyeball, usually proptosis, is the most common of the early signs and is easily discernible in most cases by inspection alone without use of instruments. Changes in the walls of the orbit or in the density of the orbital contents may be altered by tumors in such a way as to be detected by palpation or by roentgenograms. Arteriovenous aneurysm may be recognized by the bruit heard with the stethoscope or by the thrill felt by the finger over the eyeball or by both of these signs. All of these means of investigation must be utilized routinely in examination.

Other signs have to do with function of the eyes, such as motility and vision. Rotation of the eye may be impaired by paralysis of one or more of the extraocular muscles, which, in turn, may be the result of interference with the nerve supply, or of mechanical interference by involvement of the muscle or its tendon by invasion or displacement. Disturbance of ocular motility, as a rule, is not helpful in diagnosis of tumor or in the determination of the situation of the mass of the lesion, whatever its nature, whether diplopia is or is not present. Loss of vision is of great importance as a diagnostic sign only when it occurs as an early change in the course of exophthalmos. Defects in the visual fields are significant in a limited number of cases of posterior orbital involvement.

All of these signs of orbital tumor may be brought about by disorders that originate outside the orbit, such as intracranial tumors with intraorbital extension, aneurysms, cranial and facial deformities from congenital and acquired disease, maldevelopment, trauma and endocrine dysfunction. Subjective symptoms of orbital tumor such as deep pain, sense of pressure and expansive headache, numbness, loss of tactile sensation about the face and head, throbbing or pulsation and stinging burning sensation of the eyeball and lids, are seen only occasionally and may not be at all relative to the tumor but expressions of anxiety or purely functional experiences. Such symptoms however are helpful in evaluating conditions which may or may not be referable to a tumor. A study of the signs and symptoms of orbital tumors in a considerable number of cases reveals some interesting and helpful trends in making a diagnosis and in deciding on methods of treatment and surgical management.

There are three cardinal signs of tumor of the orbit which I shall discuss in the order of their importance. The first is exophthalmos, the most common of all the signs of tumor of the orbit. As exophthalmos also occurs in all cases of space-taking or expansive disorders within the orbit, anterior ocular displacement in itself is not indicative of the cause even when proptosis is altered by displacement to one side. Generally speaking, the rate of increase in proptosis is an index of the rate of growth or expansion of a space-taking lesion behind the eyeball, but when proptosis is caused by a tumor its extent is not truly indicative of the size of the lesion, as tumors of the anterior part of the orbit, particularly in the superior quadrants, will, as a rule, produce exophthalmos in the early stages of their development, and as the globe occupies most of the space in the anterior third of the orbit, any extraocular growth displaces the eyeball as long as the bony walls stand firm, while tumors of the posterior half of the orbit may acquire considerable size before appreciable proptosis occurs. This is due to the absorption of fat from compression by slow-growing tumors and freedom with which a tumor may shift its position to occupy space where resistance is low.

A tumor in the anterior half of the orbit displaces the eyeball away from the side of the orbit along which it grows forward. This may be a confusing observation. The tumor may have its origin well back of the eyeball on the opposite side from which it appears to be and may cross from one side of the orbit to the other as it grows forward. In 1 case, observed at the Mayo Clinic a few years ago, a large mucocoele of the maxillary sinus and the ethmoid cells had entered the orbit through the nasal wall, well behind the globe. Within the orbit there were a palpable firm mass in the superior temporal quadrant and proptosis of the globe with displacement toward the nasal side. There was no indication of a mass situated in the nasal side of the orbit, and the logical surgical approach seemed to be along the superior temporal rim of the orbit. A similar situation may be encountered in cases of tumor of the blood vessels and some other tumors that expand by invasion of neighboring tissue rather than as encapsulated bodies.

Proptosis without lateral displacement of the eyeball is the rule in cases of space-taking masses arising in and filling the posterior third of the orbit, particularly tumors of the optic nerve. A tumor in this region may grow to the size of the eyeball and produce considerable proptosis without lateral displacement or troublesome disturbance of rotation. This also holds true of exophthalmos caused by conditions within the orbit other than tumors unless associated with paralysis of ocular muscles.

As most tumors of the orbit are unilateral, unilateral exophthalmos may be presumed to be due to a tumor unless there is some other evident cause for it. The presumption of tumor, however, does not warrant surgical exploration of the orbit until other probable causes of exophthalmos have been ruled out and only then if there is predictable probability of danger from waiting too long. Unilateral exophthalmos of a slowly progressive character is seen in metabolic diseases that in themselves present difficulties in diagnosis, particularly goiter. Visual loss is rare in such cases in the early stages, danger of permanent injury is quite remote and surgical intervention may be safely deferred. However, surgical exploration of the orbit is often done under the impression that a hidden soft tumor is responsible

for the proptosis. The results are difficult to explain to the patient and his relatives.

Bilateral exophthalmos due to tumors of the orbits is rare but is commonly present in Mikulicz's disease and in dysthyroidism. The rate of development of exophthalmos in such conditions is of more significance in differential diagnosis than are its extent and its duration.

Angioneurotic edema begins with intermittent swelling of the eyelids. It gradually increases in severity and extent and finally produces permanent swelling of the lids and exophthalmos, which may persist for several years with little variation. In the early stages the condition resembles pyocoele of the frontal or ethmoid sinuses and surgical intervention, again based on presumption has been done without any benefit.

Lymphoblastoma usually begins in the region of the lacrimal fossa and invades the eyelids. At the first examination one may find one or both sides involved. While one side may show changes some months or years before they are noticed on the other side, lymphogenous tumors of the orbit particularly in Mikulicz's disease are with few exceptions bilateral. Of this group of neoplastic diseases frequently found to be bilateral, neurofibromatosis is most often unilateral.

Confusion in the diagnosis of orbital tumors occurs when exophthalmos is bilateral and combined with moderate swelling of the eyelids. This is the picture usually seen in exophthalmic goiter and in Mikulicz's disease. On the other hand the ocular manifestations of either of these diseases may be limited to one side. Edema of the eyelids and conjunctival chemosis may be absent. If the basal metabolic rate is low and other signs of hyperthyroidism are minimal or absent exophthalmos in a case of arrested hyperthyroidism might well be and often is attributed to tumors of the orbits. That many such mistakes have been made is evident from the reports of cases in which surgical exploration has been undertaken for removal of a suspected tumor with the result that no tumor was found. Often the reason for exophthalmos could not be determined. In such cases the condition has been referred to as "pseudotumor of the orbit." Exophthalmos due to hyperthyroidism is sometimes delayed, it occurs some months after an episode of mild general symptoms that never were severe, or even were unnoticed, and have then entirely subsided. In some cases exophthalmos associated with edema of the lids subsides without treatment and the cause of the changes in the orbit may never be known. Low grade cellulitis following dental infection and extraction of teeth is a case in point. Exophthalmos due to low grade cellulitis may last several months and subside without permanent disabling sequelae. Exophthalmos of goiter may behave in the same way, but exophthalmos due to neoplastic diseases does not subside spontaneously.

Mucocoele and pyocoele causing exophthalmos often are undiagnosed or are mistaken for tumor. The reasons for this are obvious. Mucocoele is slow in development, shows minor or no changes in the roentgenogram, produces no inflammatory reaction in the orbit and may be palpated in some cases within the orbital rim as a firm smooth mass. Dermoid cyst of the orbit is likely to be mistaken for tumor or mucocoele. To distinguish tumor and pyocoele or mucocoele may be rather difficult, as the entire symptom complex may well indicate one or the other. Neither condition, however, should be confused with inflammatory disease of the orbit or with aneurysm.

The exophthalmos of aneurysm is peculiar in onset and progress and deserves special consideration, because surgical exploration of an orbit which contains an unsuspected aneurysm may lead to serious complications. Pulsating exophthalmos due to arteriovenous connection within the cavernous sinus gives rise to a well known symptom complex that is not often missed. However, when the arteriovenous connection is within the orbit, whether due to trauma or to disease, only small vessels are involved and the distinct bruit and thrill of cavernous sinus-carotid fistula may be absent or only slight but a venous aneurysm of considerable size may develop so as to require radical surgical intervention. The outstanding features of such conditions are derived from the history rather than from examination.

Exophthalmos due to traumatic aneurysm, which sometimes follows penetrating injuries of the orbit or fractures of the skull, occurs suddenly as a result of hemorrhage into the orbit. Within a few minutes after the injury the eye is noticeably protruded and the eyelid swollen and discolored from hemorrhage. As the swelling and discoloration recede, the veins become distended and all orbital tissues become congested and the exophthalmos becomes stationary. Bruit and thrill can be detected. This is the usual manner of development of pulsating exophthalmos due to injury.

On the other hand, arteriovenous aneurysm due to vascular anomalies or disease usually develops slowly over a period of years and is accompanied by the appearance of enlarged veins over the face, a pronounced subjective bruit and a distinct pulsatile thrill. In some cases varices in the orbit take the form of sacculated aneurysms or occur as spongy cavernous tumors. Thrombosis may form in these cavernous spaces and give rise to acute inflammatory reaction, pain, swelling and increased proptosis. Discoloration of the lids will indicate whether or not the lesion has bled and is a diagnostic sign that should not be overlooked. Careful inquiry should be made regarding a history of discoloration of the skin of the lids. Pigmentation of the skin may be noted if hemorrhages have been frequent or severe. In any case of suspected aneurysm of the orbit, careful search should be made for bruit and thrill.

In some cases of aneurysm, exophthalmos can be made to increase and to decrease with exertion and change of position of the head, a condition known as intermittent exophthalmos. Exophthalmos that varies considerably in degree usually is indicative of fluid masses of some kind behind the globe. They may consist of mucus or blood. Most commonly they are found to be mucocoeles or pyocoeles that can be emptied by change in position of the head.

According to Berens,¹ "Intermittent or periodic exophthalmos is attributed to a variety of causes, the most common of which are varicosities of the orbital veins, vascular tumor, hemorrhage, cavernous angioma and recurrent inflammation. The exophthalmos tends to increase or become stationary, or to disappear, depending on the disposition of the etiologic factor."

The most striking and unmistakable syndrome is caused by aneurysm. According to Walsh and Dandy,² who recently have reported such a case, "It is characterized by pronounced and rapid, almost instantaneous protrusion of one eye when venous stasis is induced by bending the head forward, by lowering the head by

turning the head forcibly by hyperextension of the neck, by coughing, by forced expiration with or without compression of the nostrils, and by pressure upon the jugular veins. The ocular protrusion disappears immediately when the head is erect and when artificially induced venous congestion is relieved. Usually, but not invariably, there is exophthalmos when venous congestion does not obtain. There may or apparently (from cases reported in the literature) may not be pulsation of the eyeball. The vision may or may not be affected. The condition is progressive and may be productive of unbearable pain and troublesome diplopia."

In any case of exophthalmos of obscure origin the probability of tumor must be considered from two points of view: first, whether the exophthalmos can be explained on the basis of any other cause, second, whether, if it is due to a neoplasm, it is benign or malignant and is primary within the orbit or invades the orbit by extension. The problem can best be attacked by attempting first to eliminate non-neoplastic diseases. This is not always easy to do. To rule out goiter, for instance, may require observation for several months under therapy. Exophthalmos may occur during an episode of myxedema, a fact which is often overlooked. A careful history should be taken and one should look for signs of previous hyperthyroidism regardless of the age of the patient. The basal metabolic rate should be known but its significance should not be overestimated, particularly if it is low. Repeated careful measurements of the degree of exophthalmos should be recorded, and comparison of photographs taken from time to time is helpful in determining minor changes. The facial expression in thyroid disease is often a most valuable diagnostic aid when it is properly interpreted.

The mechanism of exophthalmos in goiter is well known. In about a fourth of the cases of acute hyperthyroidism, swelling of the eyelids and exophthalmos come on rather early in the course of the disease and may be the most conspicuous signs. Edema of the eyelids and conjunctivas varies from mild to extreme severity, when it is practically irreducible. In cases of acute hyperthyroidism it is practically always bilateral and in advanced stages it is unmistakable. In cases of chronic hyperthyroidism, exophthalmos quite often appears first in the posthyperthyroid period, after thyroidectomy. As a rule the lids are not swollen and there is little or no chemosis. The exophthalmos may be unilateral, with or without muscle paralysis. The mechanism of the exophthalmos in chronic goiter is the same as it is in cases of acute hyperthyroidism, namely edema of the orbital tissues. As the ocular muscles are greatly swollen, motility is impaired and bizarre muscular findings vary from week to week. Although rotation may be impaired and squint may be present, the proptosis is not altered by lateral displacement of the eyeball and vision is seldom affected. The only other signs of goiter appear in the facial expression, particularly the position of the eyelids. The characteristic retraction of the upper eyelids usually indicates to the experienced observer the cause of the proptosis.

Mikulicz's disease may closely resemble orbital changes of hyperthyroidism. There are chronic swelling of the eyelids with exophthalmos, disturbance of motility and in some instances transient chemosis. These alterations may vary in extent from time to time but are for the most part consistent and progressive. The patient may not be seriously ill, and the general symptoms such as weakness and loss of weight may be

¹ 1. Berens, Conrad. *The Eye and Its Diseases*. Philadelphia: W. B. Saunders Company, 1936.
² 2. Walsh, L. B. and Dandy, W. E. Unpublished data.

similar to those of the posthyperthyroid state. In Mikulicz's disease, however, there are nodules of infiltration that can be felt in the lids, about the eyeball or in the temporal region. The lacrimal and salivary glands are infiltrated and enlarged and there may be changes elsewhere, particularly in the thorax. Such glandular changes are not found in cases of goiter. In Mikulicz's disease the exophthalmos and the swelling of the lids rapidly disappear after the use of roentgen therapy, whereas, in goiter, irradiation has no appreciable effect in the cases in which the disease is chronic.

Other diseases that cause exophthalmos must be ruled out by local investigation of neighboring structures. A low degree of exophthalmos is common in cases in which a pituitary tumor brings about obstruction to the blood flow through the cavernous sinus. Other lesions about the optic chiasm may act in a similar manner to bring about congestion within the orbit and cause exophthalmos. Other signs of chiasmal disturbance, such as defects in the visual fields and changes noted by roentgenography, are determining factors.

Thrombosis of the cavernous sinus nearly always produces exophthalmos, but other signs are so indicative of the cause that tumor of the orbit is not suspected, particularly in the presence of fever and other signs of acute illness.

In an attempt to rule out cysts as a cause of exophthalmos, some surgeons have attempted to explore the orbit with a trocar. Although I never have employed this method of attempting to satisfy curiosity, I have seen some unfortunate results from this practice when employed by other surgeons. It is a futile procedure and I know of no condition which can be helped by it. On the contrary, great harm may be done. I know of 1 case in which an encapsulated tumor of the orbit was pierced by a trocar. When operation was performed at a later date, the patient was found to have a malignant tumor that had spread along the path of the trocar to the lids and was spreading from this tract. The encapsulated tumor originally could have been removed intact if the capsule had not been ruptured, but because of the release from its capsule the lesion spread throughout the orbit and the eye was lost. Exploratory incisions also are of little value and should not be made for diagnosis unless one is prepared to continue with whatever surgical procedures are necessary to complete the indicated surgical management.

Loss of visual acuity with preservation of vision in the peripheral field strongly indicates posterior orbital or chiasmal lesions. When central loss of vision occurs before exophthalmos appears, the chances are much in favor of the lesion being due to an inflammatory process and of loss of vision being attributed to a condition such as retrobulbar neuritis. While the possibility of tumor must be borne in mind the diagnosis of tumor rests on corroborative evidence. In the absence of ophthalmoscopic changes such as choked disk, optic neuritis, optic atrophy, retinal and choroidal disease and opacities in the media visual loss may be presumed to be due to changes along the visual pathways. The lesion may be retrobulbar and situated within the orbit. There is always the probability that it may be due to a tumor.

What visual losses are attributable to tumor of the orbit? The most common visual disturbance is lowered visual acuity. This may begin as a generalized depression of visual function, without significant changes in the visual field or as a central or paracentral scotoma. A tumor of the orbit that produces loss of vision before exophthalmos occurs must be situated in the posterior

portion of the orbit and affect the optic nerve. It may be a tumor of the nerve or its sheath or one that blocks the nerve by pressure, possibly a meningioma. Without other signs of tumor such a diagnosis obviously cannot be made. As a cause of visual loss tumors of the optic nerve are rare compared with toxemia and diseases of the central nervous system. It is not always possible to arrive at a definite conclusion in case of recent onset until after some weeks of observation.

Roentgenograms are useful in the identification of some orbital tumors. Osteomas of the sinuses that encroach on the orbit are best identified by this means. Hyperostosis of the orbital walls is brought about by tumors and diseases of the bone or of soft tissue that are situated near the bone. The most common form of hyperostosis that one sees in the roentgenogram is that of the sphenoidal ridge caused by an intracranial meningioma. Some vascular tumors that develop slowly along the orbital wall also produce hyperostosis. Such a case was reported by me and Love.³ It has been shown rather conclusively that the roentgenographic appearance of hyperostosis caused by meningioma cannot be distinguished from that of vascular tumors, although the lesion in the bone is quite different.

Erosion of the walls is the rule in cases of pulsating tumor, although in some instances I have seen thickening of the lateral wall of the orbit caused by hemangioma and pulsating exophthalmos.

Pycocles of the sinuses cause pronounced thinning of the surrounding bones that give way to the expansion of the cyst. I have been surprised in some cases to see severe distortion of the orbital walls and the sinuses with little evidence of change in the roentgenogram. In cases of draining pycocle the roentgenogram may be entirely normal.

Considerable comment has been directed to roentgenograms of the optic canals. In a large series of cases of posterior orbital tumors and chiasmal lesions in which roentgenographic examination and operation have been performed at the clinic, very few changes of note have been observed in the size of the optic canals, and these have not always been explainable by the findings at operation. One cannot be sure that a tumor has involved the optic canal because the canal is larger than its fellow.

Soft tumors of the orbit, particularly if composed of dense fibrous tissue, may be portrayed in the roentgenogram with surprising clearness. While the roentgenograms of the head are often normal in cases of orbital tumor, every case should be studied by at least lateral and anteroposterior roentgenograms.

In a large series of orbital tumors one will find rare changes about the eyes that are indicative of tumor. In doubtful cases these changes may be of considerable help in diagnosis. In the eyelids one may find lesions that are of the same nature as a tumor in the orbit. Mikulicz's disease is a case in point. The swelling of the eyelids and exophthalmos are quite similar to those seen in goiter, but nodules in the lids or firm hypertrophic masses are always present in Mikulicz's disease but never in goiter. A biopsy will be conclusive.

Epitheliomas of the lids usually are easily recognized, but deep seated carcinomas, movable and firm, which in size and position resemble lipomas are not uncommon. Such carcinomas have been known to follow roentgen therapy of superficial lesions.

3 Benedict W. L. and Love J. G. Cavernous Hemangioma of the Orbit with Hyperostosis. Report of a Case. *Am J Ophth* 22: 1149, 1151 (Oct.) 1939.

Arnold Knapp called attention to the wrinkling of the fundus caused by pressure of a tumor on the posterior side of the eyeball. I have often seen the streaks in the fundus caused by wrinkling in cases in which the fundus was pushed forward for 4 to 6 diopters. I have never seen them in any other condition than tumor.

SUMMARY AND CONCLUSIONS

The probability of tumor in any case of exophthalmos is so great that only in cases of goiter is there serious doubt of the presence of an expanding lesion. The temptation to explore the orbit is irresistible for some surgeons and an exploration is planned. This is not a surgical procedure but a diagnostic one unless the surgeon is prepared to remove the tumor and do the necessary repair. Exploration by trocar is useless and should never be done. Such a procedure is of no help in diagnosis, and in case of malignant tumor or vascular aneurysm it is positively dangerous. Puncture for digital exploration only should never be practiced. One cannot explore the orbit with the finger from any one place along the rim and be sure that nothing has been missed. Exploration of the orbit for diagnosis should always be done through an incision large enough and so placed that, should a tumor be encountered or any other pathologic condition be found that would require surgical removal, the operation can be completed at the time. If one is not sure of the presence of a tumor, it is in most instances safe to employ roentgen therapy and await developments.

THE ROENTGENOLOGY OF OSTEO-MYELITIS

J. W. PIERSON, M.D.

BALTIMORE

AND

LIEUTENANT COMMANDER J. F. ROACH
(MC), USN

Osteomyelitis is a disease which has been known to man for many long years, and during that time a great deal of clinical and laboratory investigation has been performed. Many of its mysteries have been solved, but it remains today one of the important orthopedic problems. A brief survey of the literature of just the past few years will show the advocacy of many different forms of treatment and their very number is an indication of the clinical difficulties one meets with this disease. The most recent innovation has been the advent of penicillin for which we have held high hopes, but as yet sufficient time has not elapsed to evaluate its therapeutic effectiveness.

With the thought in mind that no disease can be rationally treated unless its diagnosis is established, we would like to discuss the diagnosis of osteomyelitis, chiefly from an x-ray point of view.

The onset of osteomyelitis is most commonly seen in the age group of 5 to 20 years, the period in life during which we undergo our most strenuous physical activity. Many writers have pointed to this age incidence and related trauma as a predisposing factor. Some weight is added to this theory by the fact that

boys are more subject to the disease than are girls, and it seems reasonable to assume that bacteria may gain a foothold in traumatized tissue more easily than in normal tissue.

The usual offending organism is *Staphylococcus aureus*, though a small proportion of cases (about 10 per cent) show other bacteria, among which are streptococci, pneumococci and typhoid bacilli. The organisms may gain access to the bone in one of three ways: the first two of which we do not consider important because they do not lead to any difficulty in diagnosis. These two are (1) by contamination of the bone such as may occur in a compound fracture and (2) by direct extension of an infection of the soft tissues adjacent to a bone. The third and important method is the hematogenous. It is by this route that bacteria are carried from a primary source to their new focus in bone. The primary source may be a well established clinical lesion such as a furuncle or carbuncle, or it may be a completely asymptomatic process such as a small infected abrasion. In either event the organisms enter the blood stream and, after escaping the body's protective mechanisms, are finally deposited within the bone. There is a rather definite predilection for certain areas of the bones, and these areas are those at which the blood supply is the greatest or, in other words, where growth is most active. Thus, the first changes of osteomyelitis are most frequently seen in the metaphysis of the long bones rather close to the epiphyseal line.

With the lodging of the bacteria in the bone, a minute abscess begins. The organisms multiply, their toxins are liberated and blood vessels become occluded. These processes lead to the first change in the bone that may be seen on the x-ray film. The exact physiologic mechanism of this change is not known, but it is generally believed that the formation of a minute abscess within the bone stimulates the activity of osteoclasts in the adjacent bone, which together with inflammatory cells (connective tissue and round cell) produce the absorption of living bone. This appears on the film as an area of rarefaction, which usually is seen as a circular zone of slightly lessened density in which the normal sharp architecture of the trabeculae is beginning to lose its clearcut appearance. The time at which this change can first be seen is often said to be in the neighborhood of seven to ten days from the beginning of the disease, subject to such variable factors as the thickness of the part, the relative density of the interposed tissues and the amount of lime salts present in the bone at the time of onset of the disease.

If the virulence of the organism within the abscess is greater than the resistance of the host, the process enlarges through the cancellous bone along the lines of least resistance. If it meets the epiphyseal plate its spread in this direction is usually checked because this cartilaginous structure is very resistant to infection. At times, however, this resistance is overcome and the disease may then involve the epiphysis. Again, the infection may advance in the opposite direction and gain access to the medullary canal. This may then result in necrosis of the fatty bone marrow and a rather extensive portion of the cortex of the diaphysis. Spread in a lateral direction brings the inflammatory process to the cortex. All of these developments lead to the accentuation of the first noticeable x-ray changes. That is, the zone of rarefaction becomes more pronounced and more extensive.

In a large percentage of osteomyelitis cases a subperiosteal abscess develops, and this is produced in one of two ways, either of which may sometimes be demonstrated on the film. If the medullary canal is infected, the process may extend through the haversian canals to the subperiosteal bone. In so doing, the bone surrounding the haversian canals may be destroyed, thus forming a demonstrable channel. The second route of spread to the subperiosteal region occurs in the cancellous bone. When the abscess spreads laterally it meets the cortex, which it necroses and perforates, thus allowing the escape of the infection to the subperiosteum.

Occasionally an osteomyelitic process may begin directly beneath the periosteum, and in these cases a rather extensive abscess may form before any changes can be demonstrated on the x-ray film. Once the inflammatory process has gained access to the subperiosteal bone, it strips this membrane away from the cortex. The extent of this stripping is quite variable but it may go so far longitudinally as to involve the entire shaft and it may also completely surround the bone. However, the subperiosteal abscess almost never extends beyond the epiphyseal line at either end, for here the periosteum is very firmly attached.

The development of the subperiosteal abscess leads to another x-ray sign. When the periosteum is separated from the cortex it carries with it many osteogenic cells, which now receive their nourishment from the rich periosteum. These cells are stimulated to activity and promptly begin to lay down a thin layer of bone. This process is so rapid that in a great many cases sufficient new bone to show on an x-ray film is produced in about a week. This new bone is first seen as a thin zone of calcification parallel to the cortex. Where the periosteum has been extensively stripped away from the cortex this new bone may form a sheath surrounding the old bone and dead bone or sequestrums may be entirely enclosed.

A similar physiologic process that is the stimulus of living bone cells to form new bone in the presence of infection leads to the third x-ray change. The osteogenic cells of both the metaphysis and the diaphysis in the infected and adjacent areas begin to produce new bone. This leads to two characteristic changes. First as new bone is laid down the bone becomes thickened in its cortical portion and the trabeculae in the cancellous portion become heavier. Second, the haversian canals and the fibrous spaces between trabeculae may be filled with new bone and thus obliterated. These processes lead to a thick, sometimes ivory-like bone. A film of such a bone shows it to be heavier and denser than normal.

To summarize the process thus far it can be said that pyogenic organisms are carried to the bone by the blood stream. There they set up an abscess which leads to absorption of bone. The abscess then spreads and may reach the periosteal region by direct extension through the cortex or via the medullary cavity and the haversian canals. Thus a subperiosteal abscess is set up. While these processes are going on reparative attempts are made by the bone, and these manifest themselves by periosteal and endosteal bone formation.

These acute changes sometimes subside spontaneously or with treatment but frequently they fail to do so and then the picture of chronic osteomyelitis prevails. This tendency to chronicity is brought about chiefly by the anatomic and pathologic conditions involved. Bone which is killed by the acute infection is absorbed with great difficulty and this remains sometimes free in the

abscess cavity and sometimes incorporated within new bone. The infected dead bone may lead to chronic draining sinuses or it may be completely sealed off. In the latter case it is possible for living organisms to remain viable for many years with the ever present possibility of flaring up again into acute activity. The x-ray appearance of chronic osteomyelitis is that of a heavy dense bone which looks somewhat moth eaten. Sequestrums or pieces of dense ragged dead bone may be seen lying free or incorporated in the new bone formation.

If the organisms which reach the bone are of low virulence when compared to the resistance of the tissues a similar but less extensive process results. Here as before an abscess forms but its spread is considerably limited by the surrounding bone. Thus we have a localized osteomyelitis which shows many of the x-ray changes previously noted but to a lesser degree. The radiolucent zone produced by absorption is seen and sclerosis of bone is present in the adjacent area. If the abscess lies near the cortex the periosteum may be stimulated sufficiently to produce the formation of new periosteal bone. Here the process usually stops and the extensive changes of chronic osteomyelitis are not seen.

Another form of osteomyelitis that is occasionally seen is Garre's or chronic sclerosing osteomyelitis. In this disease there is quite a different pathologic process and thus a different x-ray picture. The infection is primarily a diffuse process involving a portion or all of the shaft of a bone. Usually no abscess is found and the disease manifests itself on the x-ray film chiefly by its bone producing activities. The osteogenic cells of both the periosteum and the cortex are stimulated and the new bone which is laid down produces a very heavy dense structure. This process may be extended to produce almost complete obliteration of the medullary canal.

The x-ray diagnosis of osteomyelitis is unfortunately not always simple, and changes which occur early in the disease are frequently mimicked by several other pathologic states. It is important, though not always possible, to differentiate these because in almost every instance both the prognosis and the accepted treatment differ greatly from those of pyogenic osteomyelitis. From an x-ray point of view there are three groups of diseases which frequently cause differential difficulties. These are (1) other infections, (2) bone tumors and (3) diseases of the reticuloendothelial system.

In considering other bone infections there are two which cause most of the difficulties. The first of these is syphilis in either the congenital or the acquired form, and it is the tertiary stage of these conditions which may simulate so closely the changes of osteomyelitis. Syphilis begins in the bone as a periosteal infection which stimulates the periosteum to proliferate new bone. In addition there is a true osteitis, which results again in bone osteogenesis in the cortical and medullary bone. Gumma, single or multiple, may appear and destroy bone, thus the final result of these processes as seen on the film is a thick irregularly dense moth eaten bone which may completely simulate the picture of osteomyelitis, and it is frequently impossible to differentiate the two without the aid of the clinical findings.

The second bone infection which offers diagnostic problems is tuberculosis. Usually tuberculosis of bone is not a difficult diagnosis to make, but in the relatively rare tuberculous osteomyelitis of a long bone a picture

closely resembling pyogenic osteomyelitis may result. There is one very helpful factor in differentiating tuberculosis, and that is that its bone destructive qualities usually surmount its bone producing activities. Thus on the film we are more apt to see radiolucent bone rather than the dense sclerotic bone of pyogenic osteomyelitis. However, it occasionally happens that a tuberculous abscess develops in a long bone, usually in the metaphysis. This may then go on to produce bone absorption, periosteal bone proliferation and endosteal bone formation. It is readily seen that these processes may produce the so-called characteristic picture of osteomyelitis.

Bone tumors form the second group of diseases which must be considered in conjunction with pyogenic osteomyelitis, and we are of the opinion that these are the most important conditions for differentiation. Here the prognosis is of course grave and incorrect diagnosis may lead to a sorry situation.

There are many forms of bone tumor, but we propose to discuss here only those which offer the greatest diagnostic problems. There are several clinical similarities of bone tumors and osteomyelitis which add to the difficulties of diagnosis. The peak age incidence of the two groups is just about the same, and the location of the disease tends to follow a similar pattern. The onset of clinical symptoms may be identical in the two conditions. Thus we may see a young patient with the symptoms of acute osteomyelitis even with an elevated white blood cell count, and if one is not careful a diagnosis of osteomyelitis may be made when the underlying pathologic condition is really that of a bone cancer.

The first tumor we should like to consider is osteogenic sarcoma. This tumor arises from the osteoblast of the periosteum and in many cases the predominant cell depends on the stage of development of the osteoblast at the time the tumor began. This however is not always the rule and a tumor may frequently change its cellular characteristics as the neoplasm advances. Thus we may find a growth which shows a preponderance of fibrous tissue, cartilage or bone, or a mixture of these three. If the tumor consists primarily of only one of these tissues, the x-ray picture is differentiated from osteomyelitis without too much difficulty. However, in the mixed types a different situation exists. The most confusing picture occurs when the tumor invades the bone early in the disease and produces bone destruction. When this is coupled with new bone production within the tumor and along the periosteum a pathologic process is encountered the x-ray appearance of which taxes the most astute diagnostic eye. We often hear of the "sunburst" picture of osteogenic sarcoma, and when this occurs the diagnosis is usually easy. However, new bone formation in spicules perpendicular to the cortex is not limited to osteogenic sarcoma nor is it always present in this disease. Any disease process which slowly lifts the periosteum from the bone so that the capillaries which run from the periosteum into the bone are not torn away and then new bone is apt to be laid down along the course of the capillaries. Thus one sees that the physiologic mechanism of the sunburst effect is not limited to any one pathologic state.

A second tumor of bone to be considered is Ewing's sarcoma, or preferably Ewing's endothelioma. The exact source of origin of this tumor has long been a disputed point but today most workers believe that it is not a true sarcoma and that it arises from the endothelial

cells of the blood vessels or lymphatics of bone. Although the growth may begin subperiosteally, it usually arises within the medullary cavity. In the latter case, while it stays within the confines of the cavity no x-ray changes are demonstrable. However, it sooner or later invades and destroys adjacent bone, and when the growth approaches the subperiosteal zone the periosteum is stimulated to activity and new bone is laid down. In addition, where bone is being destroyed there is also the stimulus to produce new bone, and though this is minimal in Ewing's tumor it nevertheless is present. It is at this stage in the development of the cancer that the greatest x-ray problems are encountered, for here just as in osteomyelitis we find the same three changes on the x-ray film, namely bone destruction, bone formation and periosteal proliferation.

A third tumor which occasionally offers diagnostic problems to the radiologist is the metastasis of neuroblastoma. It is the early stage of the single metastasis which causes the most difficulty. It is true that the growth is primarily osteolytic, but, as is always seen in bone destruction, the impetus to produce new bone is present and the final result may be a pathologic process the x-ray appearance of which is not at all unlike that of osteomyelitis.

There remains one group of diseases which may simulate the changes of osteomyelitis and this group includes several related entities all of which show either primary or secondary changes in the reticuloendothelial system. This group includes the leukemias, the lymphomas, the xanthomas and the congenital anemias. The characteristic x-ray picture of any one of these is usually readily differentiated from the others and from osteomyelitis, but each may have a stage in its development when one sees bone destruction, bone production and periosteal reaction in other words the picture of a relatively early osteomyelitis.

SUMMARY

Osteomyelitis produces changes in the x-ray film which can be explained on a sound physiologic and pathologic basis, and these changes are usually sufficiently characteristic to lead to a correct diagnosis. There is, however, a definite stage in the early development of hematogenous osteomyelitis when the x-ray picture is one which may be closely mimicked by several other pathologic conditions. It is unfortunate that this period is frequently at a time in the course of the disease when clinical symptoms and signs do not point to a definite diagnosis. Furthermore, the nature of several of the diseases whose films parallel those of osteomyelitis is such that a mistaken diagnosis and the resultant incorrect therapy may bring on a very unfortunate end result.

1107 St. Paul Street

The Heart—When the modern physician speaks of the cause of death as cardiac or respiratory, he refers to the mechanical failure of these organs to continue performing their normal function. But when the ancient man spoke of these organs as not active he was alluding to the departure of the soul from them without any regard to their functional condition. The difference between life and death was the silence of the heart-beat a phenomenon primitive man could not miss and the cause of which he could not explain except by the presence of the soul in the organ. The heart therefore, was considered by many ancients the source of emotion, intellect, wisdom and courage—Gordon, Benjamin Lee. *The Romance of Medicine*, Philadelphia F. A. Davis Company, 1944.

SURVEY OF MEDICAL CARE IN A
WAR INDUSTRY AREA

MALCOLM H. MERRILL, M.D.

Chief, Division of Laboratories, California State Department
of Public Health

AND

MARTIN MILLS, M.D., M.P.H.

Chief, Bureau of Crippled Children, California State Department
of Public Health

BERKELEY, CALIF.

The exigencies of war have placed a real strain on medical services and facilities throughout the country. This is particularly true in some of the war industrial areas that have experienced considerable increases in population. The extent of this strain in one Pacific Coast area is indicated by the data given here.

The study was undertaken by the California State Department of Public Health at the request of the Coordinating Committee on Medical Care of the California State Procurement and Assignment Service for Physicians, Dentists and Nurses. It was designed to provide information relative to the overall medical care situation in the area under study, with particular emphasis on the adequacy of physicians.

The picture had been somewhat clouded by the fact that an unknown proportion of the population was provided medical care under a prepayment plan. It had not been possible to determine even approximately the population remaining to be cared for through private practice channels.

The study was designed to provide information in the following areas:

1. The total population to be cared for.
2. The proportion of the population reached through the prepaid medical care plan and through private practice channels.
3. The physician personnel available to care for each of these two segments of the population.
4. The volume of service being rendered each group (prepaid medical care group and community at large group).
5. The adequacy of hospital facilities.
6. The consumer reaction to medical care being received.

MATERIALS AND METHODS

The survey covered the area comprising the cities of Richmond, El Cerrito and San Pablo in Contra Costa County, Calif. The Permanente Metals Corporation comprises the most extensive industry in the area, although there are a number of other large industries, as oil refineries and automobile assembly plants. The survey was conducted during the week of Jan. 17-22, 1944. The data on patients seen by physicians were for the preceding week of January 9-16, inclusive.

The survey team consisted of three physicians, one public health nurse and one medical social worker. Data were collected from physicians by a personal call to each physician's office, during which visit a questionnaire was completed which showed the number of patient visits to the office and home calls made by the physician the preceding week. The data from the pre-

The opinions expressed in this report are those of the authors and do not necessarily indicate the opinions of the Coordinating Committee on Medical Care of the California State Procurement and Assignment Service for Physicians, Dentists and Nurses for which committee the survey was made.

Dr. Edith Young, Miss Nadine Small and Miss Helen Hall assisted in the field work in this study. Dr. Harold A. Fletcher, chairman of the Procurement and Assignment Committee, Dr. Milton Rice, Dr. W. P. Shepard, Dr. Wilton L. Halperin and Dr. Morton Gibbons were members of the subcommittee appointed to assist with the survey and gave valuable suggestions and assistance.

paid medical plan of the Permanente Foundation were taken from the December 1943 monthly report of that organization supplemented by data prepared by representatives of that organization. Hospital data were obtained by direct visits to the hospitals and interviews with hospital superintendents. Other medical care agencies, such as the local chapter of the American Red Cross, the local community health center, the health department and the county welfare department were visited by representatives of the survey team and opinions obtained from workers in these agencies and from patients and other people being served during a three day period by these agencies.

The consumer reaction to the medical care being received in the area was sampled by means of a questionnaire distributed through the sixth grade students of the public schools in the area. The same questionnaire was used in the offices and clinics of the health and welfare agencies just noted. It was also completed on a limited number of families contacted by direct home calls.

The Regional Housing Authority and its constituent units were also contacted and medical care problems coming to the attention of this agency noted.

POPULATION DATA

The most recent and reliable population estimates obtainable were for Richmond 105,000, El Cerrito 16,626 and San Pablo 20,000, with a total for the area surveyed of 141,626.

For the purpose of the compilation of data the figure 140,000 was adopted as being probably the nearest round figure estimate of the population. It appeared that this was at least within 10,000 of the then current actual population and probably was a conservative estimate. The current population for the area represents approximately a threefold increase over the 1940 census.

SOURCE OF MEDICAL CARE

From a study of the total shipyard population and geographic distribution of residence of shipyard employees and knowing the percentage covered by the prepaid medical plan, it was estimated that 28,000 people living in the survey area received medical care through the prepayment plan of Permanente Foundation. This left 112,000 in the community at large to be provided with medical service.

PHYSICIAN POPULATION

It was found that 29 physicians were engaging in private medical practice in the area. Several of these were formerly retired physicians who were seeing very few patients, others maintained offices outside the surveyed area and therefore devoted only part time in the area. A study of the practice of each physician was made and the percentage effectiveness of each estimated. On this basis it was estimated that there were 24 fully effective physicians available for private practice in the area.

By applying similar estimates it was found that approximately 60 fully effective physicians were caring for the 71,139 patients covered by the Medical Plan of the Permanente Foundation.

PHYSICIAN-POPULATION RELATIONSHIP

Using the foregoing figures, the physician-population relationships are shown in table 1. These figures indicate that there were approximately four times as

in any physicians per unit of population available to the shipyard workers as to the population of the community at large

VOLUME OF MEDICAL SERVICE PROVIDED

In order to estimate the total volume of the patient load seen in the office and at home, each physician in the area was asked to provide information on the number of patient visits to the office and the number of home calls made during the preceding week. In most instances actual figures were given day by day. In

TABLE 1—*Physician-Population Relationship in the Richmond, El Cerrito, San Pablo Area of California January 1944*

	Community	Permanente Foundation
Population to be served	112 000	71 139
Total physicians available	24	60
Population per physician	4 666	1 186

other instances estimates were given. Since the latter compared quite favorably with the actual counts from comparable practices, this estimate is thought to be fairly close to the actual facts. In arriving at these figures our table was compiled, giving age of physician, type of practice, daily office visits and daily home visits. Hospital cases were not included.

For the Permanente Foundation the December monthly report, which was provided to us, was the source of the data. It is emphasized that these figures give only quantitative information and in no way indicate the intangible qualitative factors, which latter we did not attempt to evaluate. The data are shown in table 2.

The figures shown are exclusive of the work done at the first aid station at the shipyards, for which 6 physicians were employed full time. Using these figures, which would appear to represent essentially comparable services, the office or clinic and home calls per physician per month were calculated by dividing the number of visits by the number of physicians providing the service. These are figured on a basis of what has been estimated to be 100 per cent effective physicians and also eliminating the 6 physicians at the first aid station. These figures are also shown in table 2.

TABLE 2—*Volume of Medical Service Provided in the Form of Office Visits and Home Calls*

Volume of Service Rendered	Community	Permanente Foundation
Total estimated office or clinic visits per month	25 350	34 610
Total estimated home calls per month	1 950	1 470
Total office or clinic and home calls	27 300	36 080
Number of physicians providing service	24	60
Patient visits per physician	1 137	601

If the services rendered at the first aid station at the shipyards are also included, a somewhat different comparative picture is presented. For the month of December a total of 130,652 patient visits to first aid station clinics and home calls were recorded in the Permanente report. Using this figure the patient visits per physician at Permanente becomes 130,652 divided by 60, or 2,177.

We were also interested in calculating the volume of medical service per thousand of population for the two population groups. These calculations are shown in table 3. The figures in table 3 demonstrate that on

a strictly quantitative basis the subscribers to the Health Plan were seeing a physician much more frequently than were the people in the community at large. If the service rendered at first aid stations is included, there were almost seven times as many patient visits per thousand of population in the Permanente group as in the Community group. This difference is only half as great if the industrial cases are excluded from the Permanente group, since 50 per cent of all treatments given by the Permanente physicians are industrial in nature. It would appear that for illness of non-industrial type the subscribers to the Medical Plan receive three to four times more medical treatments than do people in the community at large if the service rendered at the first aid stations is included. If first aid stations and industrial services are excluded the visits per thousand of population are almost comparable (244 vs 254).

PHYSICIAN OPINION RELATIVE TO ADEQUACY OF MEDICAL CARE IN THE AREA

All physicians practicing in the area were interviewed either in person or, in a few instances, through telephone calls. An attempt was made to estimate the number of requests for service that are turned down.

TABLE 3—*Volume of Medical Service per Thousand of Population in the Community and Permanente Population Groups*

	Community	Permanente Foundation	Nonindustrial Only
Estimated population served	112 000	71 139	
Estimated clinic and home calls (exclusive of first aid stations)	27 300	36 080	18 000
Visits to physicians per thousand of population	244	508	254
Home calls per thousand of population	17.4	20.1	
Total service including first aid station		130 652	60 376
Total treatments per thousand of population (clinic, home and first aid)		1 840	970

daily. It was estimated that at least 100 calls per day, or approximately 2,600 to 3,000 per month, are not being accepted. Our impression is that this figure is extremely conservative. All physicians expressed concern over the pressure of work, and several wondered how long they might be able to keep going at such a pace. We found the waiting rooms of most doctors visited filled to capacity, and in some instances patients were waiting in the halls.

The majority of the physicians expressed the opinion that additional doctors should be assigned to the area. The most urgent need expressed was for some relief from the late afternoon, evening and night calls. Some type of an emergency setup whereby the evening and night calls could be taken care of was almost unanimously proposed. The present handling of emergency work was considered by all as being quite inadequate.

Most physicians felt that the assigning of additional doctors to do general practice would do little to remedy the situation unless a significant number is assigned, as the demand for medical service would pyramid as the service became more available. No one ventured an opinion as to the total demand for medical service if it were readily available.

Physicians who had been brought in to work in the emergency room of the Richmond Hospital had built up practices so rapidly that within a month or so they were no longer interested in remaining at the hos-

pital on an emergency basis. Indications were that it would take about a physician a month to keep this service going unless the assignment was made under an arrangement that would guarantee continued service in the emergency unit.

A significant number of physicians were much concerned over the lack of adequate hospital facilities. Lack of facilities for care of emergency cases was repeatedly mentioned. There were several comments that beds for colored patients were particularly difficult to obtain.

Opinions concerning night calls varied from statements that many of the night calls were unnecessary to assertions that the chief difficulty was that patients wait too long before calling a doctor. There were some opinions expressed that patients do not know how to go about getting a doctor.

In addition direct interviews were held with Housing Authority representatives, representatives of the residents in the housing units and by direct home calls to over 100 homes scattered throughout the area.

The questionnaire was distributed through the following channels:

1 Through the sixth grade of nine selected schools which draw students from the major residential areas.

2 To the mothers attending well baby conferences covered by the public health nurses of the health departments.

3 To patients at the clinics at the Richmond Health Center.

4 To the mothers who bring their children to child care centers that are under the direction of city school nurses.

5 To persons calling for assistance, during the three days of the survey, from the Contra Costa County Social Service Department and American Red Cross.

TABLE 4—Items Included in and Data Tabulated from Questionnaire Distributed Throughout the Area Surveyed

Total questionnaires distributed	Schools			Other		
Total questionnaires returned	1 640			260		
Total number of people represented	914 (56 7%)			260		
Average number per family group	4 400			830		
	4 9			3 6		
Answers checked						
	Yes	Percentage	No	Yes	Percentage	No
1 Do you have a family physician where you now live?	300	39 3	510	102	39 2	158
2 Have you or one of your family seen a local physician for the purpose of obtaining medical care within the past year?	600	70 0	264	220	83 2	39
3 Where was the doctor seen?						
Office	461	47 0		106	40 1	
Home	246	22 4		81	23 4

HOSPITAL SERVICE

From the initial conference in the area to the end of the survey the problem of lack of hospital facilities was constantly brought to our attention. Visits were made to all hospitals in the area. Total bed capacity and percentage of occupancy were determined and availability of hospital service was studied. Opinions of representatives of various agencies, physicians and hospital administrations were elicited. The composite picture served to indicate an acute shortage of hospital facilities for the expanded population. The problem however was quite confused owing to the utilization in varying degrees of hospital facilities of the contiguous Oakland-Berkeley area. For this reason no statistical data are included in this report.¹

CONSUMER OPINIONS CONCERNING MEDICAL CARE

Information bearing on the attitude of the public in the area concerning the adequacy of physician and hospital service was obtained from several sources. A questionnaire was distributed through several channels.

1. The data compiled are available in the mimeographed report used by the state Procurement and Assignment Service.

In items 2 to 5 inclusive it was possible to have some one who had been in conferences concerning the survey actually on hand to answer questions and assist in completion of the questionnaire and to record problem cases. These groups were designed to serve as a check on the data obtained through the schools. The summary tabulation is given in table 4. The data tabulated from the questionnaire are divided into those sent through the schools and the remainder covered under items 2 to 5 inclusive.

The results of all questions are shown in the table except 5c the second part of questions 6 and 9 and question 10. It will be noted that only 55.7 per cent of the forms distributed through the schools were returned. It may be argued that this does not therefore represent the true picture, as the results may be unduly weighted by persons who did not encounter difficulties. The fact that comparable results were obtained from the remaining groups in which there was 100 per cent return of questionnaires is indicative that the school results are representative. It must be borne in mind, however, that these questionnaires provide information only on family groups. Single men groups, elderly per-

sons and married people not having children in school are not represented

It will be observed that approximately 60 per cent of the families did not have a family physician. In over 70 per cent of the families some member had obtained medical care in the past year. About 65 per cent of these physician visits were made in the office and home. Almost 17 per cent of the one group and 32 per cent of the other group had encountered difficulty in obtaining a physician. Attempts to get a doctor were successful in only about 70 per cent of instances. Approximately one fourth of the people had failed to call a physician when needed. Some of the reasons noted for not calling a physician are given later. Slightly over 20 per cent of families had had one or more members in the hospital during the past year. Eighty per cent stated they had been able to obtain hospitalization when needed.

Under 5b as many as 30 calls to physicians were recorded before one was obtained and other figures noted were 20, and in several instances 10, 9, 8, 6 and 5.

Under 5c the waiting period varied from a few minutes to fifty-four days, but periods over twenty-four hours were noted in only 29 instances out of the total questionnaires returned. In 26 instances it was reported that the physician failed to call after the patient was advised he would do so.

Under question 6, persons were asked to state the reason why they had not called a physician. There were 143 answers given to this question. In 31 instances it was stated that doctors were too busy or so overworked. 24 stated that physicians were too difficult to get, 21 indicated that doctors would not make home calls, in 12 cases it was noted that one had to wait too long to get to see a physician. 6 times the comment was noted that appointments had to be made so far in advance, 5 stated that they did not know any doctor in this area, 5 others that there were not enough doctors, and 5 stated that it took too much time to get a doctor, in only 5 cases was an economic reason given for not calling a doctor. The remainder were various reasons mostly revolving around the general problem of time and difficulty involved. In only 1 case was poor transportation mentioned.

The following figures are those noted indicating wait before hospitalization was obtained. Days, three, three, two, five and seven. Weeks, two, two, two, four and two. Months, three and three.

There were 158 comments recorded in response to item 10. Owing to the wide diversity of opinions, no attempt at classification has been made. In general they followed the same pattern as those noted under question 6. Difficulty in getting a doctor for emergency and night service, the long waits in doctors' offices, statements concerning doctors being overworked, difficulty in getting immediate hospital service and shunting from agency to agency were comments most frequently noted. In a significant number of instances it was commented that the shipyard workers are fairly well taken care of but that there are not enough doctors for their families. In several instances it was stated that workers are leaving the area because of lack of doctors and medical care. Surprisingly few of the comments appeared to be of the complaint type.

As indicated, the data obtained from the questionnaires was supplemented by direct interviews. In these interviews specific case histories were obtained in an effort to determine the exact problems when there was difficulty encountered in obtaining medical attention.

The representatives of one of the housing unit citizens' associations provided a number of such specific case histories. These merely substantiated the statements noted on the questionnaires that it was very difficult to obtain physician service for evening and night home calls that in occasional cases real emergencies encountered considerable delay in achieving medical attention, that there were frequently long waits, whether in doctors' offices or at the Permanente Hospital clinics.

In another group of direct interviews 102 direct home calls were made in various areas of the city. These visits only served to confirm the general trend of information obtained from the questionnaires. The same general problems were encountered and a number of problem cases were cited. These revolved for the most part about the difficulty and delay in securing physician and hospital services.

OFFICIAL HEALTH SERVICES

There were repeated comments encountered throughout the survey concerning the inadequacy of the local health department. It was found that despite the fourfold increase in population in the city of Richmond the health department had less personnel than at the beginning of the war. Since the survey, the health department has been completely reorganized and has become much more adequately staffed.

COORDINATION OF SERVICES

Repeated comments were heard relative to lack of coordination of even existing medical facilities and services. Each agency has been carrying on its own activities, frequently without regard to other agencies. There has seemingly been considerable reluctance to accept responsibility by the various agencies. The need for a medical coordinating council or central medical clearing agency was repeatedly expressed by various persons interviewed. In several instances it was suggested that this should be the city health department.

Many of the interagency complaints and criticisms appeared to members of the survey staff to be based on inaccurate or inadequate information or frank misunderstandings. It appeared that perhaps the majority of such problems could be readily resolved if representatives of the various agencies could come together, define the limits of their respective responsibilities and discuss the areas wherein friction develops.

COMMENT

The problems in medical care presented in the district considered in this study are particularly interesting because of the coexistence of a prepaid medical care plan covering a considerable segment of the population alongside the private practice system serving the remainder of the people. The data that have been presented demonstrate that the recipients of the prepaid medical plan are receiving a much greater volume of medical attention than are the people in the community at large. The Permanente Foundation was in operation in the Richmond area before the program of the Procurement and Assignment Service was inaugurated. We were advised by the chairman of the Procurement and Assignment Service that it had been recognized that the Permanente Foundation was fulfilling a critical need in the area by way of insuring the continued effectiveness of the workers in the vital shipbuilding industry. Therefore the Procurement and Assignment Service had cooperated in every way to insure the continued effectiveness of the Permanente Foundation program during the present emergency. This probably accounts for the allowance of one phy-

sician to 948 employees in the shipyards, in contrast to one physician to 4,666 civilians in the community at large

Ciocco and Altman² have reported statistics on the patient load of private medical practitioners in Maryland, the District of Columbia and Georgia. These data were compiled from surveys conducted near the end of the first year of the war (August to December 1942). Since that time the problem of providing adequate physician service has become much more acute in many areas of the country. This is particularly evident from the study of physician population and load of medical work being done in the areas here studied. Whereas these workers found that the average weekly patient load was 111 in Georgia, 115 patients in Washington, 119 in Baltimore and 132 in Maryland, the patient load of the physicians in the area here studied was at least twice this number (1,185 per month). These authors also indicated that in order to maintain the then current volume of service the number of persons per physician could not be increased beyond 1,200 and 1,500 in Maryland and 2,000 to 2,400 in Georgia. It should be noted that this had been increased to 4,666 persons in the surveyed area here reported. The data clearly indicate that the demand for medical service is not being met, just as the demand for many services and commodities in other fields during this wartime period are not being met. Despite these facts there were relatively few cases brought to the attention of the survey team indicating real suffering or indicating real danger to the life and health of people in the community as a result of the limited medical service available. It would thus appear that there is a rather wide margin between the level of medical service that the community has been accustomed to and the service that on a temporary basis at least will result in significantly endangering the health of the community.

It would appear that in this war industrial area the cost of medical care was at the time of the survey not a significant factor. As already indicated, in only 5 instances was this factor even mentioned by people interviewed or on the questionnaires returned. For this reason the comment has already been made that the total volume of medical care that would be utilized if it was readily available could not be estimated.

It might be noted, however, that with a fourfold increase in the population there had actually been no increase in physicians in civilian private practice. This fact, coupled with the increased average income of the population, would seem to indicate that in all probability at least four times as many physicians in private practice would be kept busy if they were available.

If we apply to the area under study the calculations of Ciocco and Altman for the Maryland area, we have the following comparisons. In Maryland approximately 500 patient visits per physician monthly was estimated to be the reasonable maximum. In the surveyed area approximately 1,100 patient visits per physician monthly were recorded. The authors calculated that 1,200 to 1,500 persons per physician was a reasonable maximum in order to maintain the approximately perwar level of service. In the surveyed area there were approximately 4,700 persons per physician. Thus despite the fact that physicians were seeing twice as many patients there were still less than half as many

total visits per thousand of population in the surveyed area as in the Maryland district studied by Ciocco and Altman.

Another factor that complicates the picture of medical care in the area surveyed particularly in the war industry group is the fact that workers in these industries have been recruited from rejects for military service, from the older age group of the population from women workers who are not accustomed to the type of work in which they are engaged and from areas in the Southern states where the level of individual medical care appears to have been low, resulting in the accumulation of illnesses and defects requiring medical attention. Thus there has been a selection of a population needing medical care. All these factors have resulted in an increased demand for medical care particularly on the part of the shipyard workers. These factors, plus the more ready availability of the service and greater number of physicians per unit of population probably account for the fact that there were seven times as many services rendered under the shipyard health plan as were received by the civilians in the community at large.

Another factor that was frequently called to the attention of the survey group was the fact that individuals from the area mentioned were not too well acquainted with how to utilize the medical facilities that were available. Many of these people do not know what to expect from a physician, are reluctant to follow advice and have no confidence in medical care provided, with the result that local physicians had become reluctant to handle them. In many instances it was found that patients had resorted to subterfuge and misrepresentation in order to secure medical service. In some of the housing districts some of the physicians were reluctant to accept calls at all, owing to such repeated instances of such subterfuge and misrepresentation.

The study also indicated that the Negro medical care problem was very acute and that facilities for the care of these people, from the standpoint of both hospital and medical facilities, were quite inadequate. There had been a considerable influx of Negro population within the preceding six to nine months into an area that had been almost entirely composed of white persons in the past. The facilities for their care had not kept pace with such an influx.

Another interesting item noted was that physicians frequently complained that patients waited too long before calling, yet at the same time there were numerous complaints that the majority of the calls were unnecessary. It is probable that the majority of the people could hardly be expected to differentiate between serious and minor illnesses. The general level of lay education in the medical field will probably have to be increased before any headway could be made in solving this problem.

Another factor that stood out in bold relief was the apparent lack of information concerning the medical services that were available. The community organizational and coordinating services had not kept pace with the expansion of the population.

One of the interesting findings was that we encountered so little in the way of complaints on the part of the public regarding the limited medical services that were available. Everywhere there was encountered the attitude that this limitation was part of the problem of being at war. With rare exceptions there was a feeling of sympathy toward the physicians of the community and a desire to limit request for service to real

problems in order to save the time and effort of the physician. This was particularly true in the population group dependent on physicians in civilian practice. There were hardly any complaints registered regarding the quality of the care once a physician was secured.

ADDENDUM

Dr Harold A. Fletcher has provided the authors with the following information relative to action taken by the Coordinating Committee following the submission of the survey report and has granted permission for it to be added as an addendum to this report.

"The Coordinating Committee of Procurement and Assignment Service sent a copy of the survey and the conclusions of the Committee to the Council of the California Medical Association. The Coordinating Committee recommended and urged that the California Medical Association take steps within itself and its component county medical societies to remedy the shortage of medical care. The Council of the California Medical Association immediately requested the California Physicians' Service to institute an emergency medical care service in Richmond to cover that large element of population which was not receiving medical care from either the local physicians of Richmond or the Permanente Foundation program. The California Medical Association financed the inauguration of this service by California Physicians' Service and underwrote any deficit which might occur for a period of ninety days or longer if the needs required. The California Physicians' Service inaugurated this service on May 1 in spite of a good many delays and obstructions due to difficulties in obtaining quarters, telephone service, etc. During May, one full time physician and one full time nurse were on duty from 6 to 11 in the evenings and from 2 on Saturday afternoon to 8 o'clock on Monday morning. This service was carried out in spite of not having a telephone exchange. Patients were charged fees on the basis of a modified fee schedule. The income for the month of May was \$134.50 and the operating expenditures were \$1,135.00, a loss of \$1,000.50. During June a twenty-four hour service was initiated seven days a week, with two physicians and two nurses, one physician sleeping in the center. Ten thousand cards notifying families and groups of the availability of the medical service were distributed. Total income for the month of June was \$402 and the total operating expense was \$1,553.35, an operating loss of \$1,151.35. During the month of July there were two doctors and two nurses for the same service. The income was \$934.40, with an operating cost of \$1,865.00. Operating loss was \$930.60. There has been a steady increase in the number of patients applying to this service for medical care, but as yet there is a definite operating loss which the California Medical Association is underwriting. It is hoped that, with the preliminary stages of this service overcome, the service will be a self-supporting project, and it is hoped that the California Medical Association will continue its backing until this result is obtained. It may be stated, however, that unless the service becomes self supporting in a reasonable period of time the question arises as to whether this added service was as necessary as would appear from the information revealed in the survey."

It should be noted that the service described was established for emergency medical care only. During the first three months of operation there were only 13 calls per patient. Patients were referred to other physicians in the community for any conditions requir-

ing follow-up care or hospitalization. There is perhaps some question whether or not such a strictly emergency service can be made to pay its way. Some plan of municipal subsidy may be necessary if this service is to be maintained.

Clinical Notes, Suggestions and New Instruments

INTRAHEPATIC OBSTRUCTIVE JAUNDICE FOLLOWING MAPHARSEN WITH DEVELOPMENT OF A SPRUELIKE SYNDROME

CAPTAIN EDWARD D. FREIS AND MAJOR DWIGHT A. MATER
MEDICAL CORPS ARMY OF THE UNITED STATES

In a case of jaundice it is of paramount importance for the surgeon to differentiate extrahepatic biliary obstruction from other causes, since the decision to operate frequently is decided by this criterion. Fairly accurate indexes for such differentiation are available, but occasionally the information obtained will be misleading. Such is the series of cases of postarsphenamine icterus reported by Hanger and Gutman.¹

Their cases presented the typical clinical and laboratory evidence of obstruction to the extrahepatic biliary tract, and for that reason several of their patients were operated on. No obstruction was found in these cases, however, other than pronounced bile stasis in the canaliculi of the liver.

The importance of preventing unnecessary laparotomies prompts us to draw attention again to the syndrome of intrahepatic obstructive jaundice. For this reason we wish to place on record a case which was typical of those described by the authors mentioned and which also presented for a time in the clinical course some of the manifestations of sprue.

REPORT OF CASE

A Negro aged 27 was found to have positive Kahn and Wassermann tests for syphilis on induction into the Army. Treatment was begun with mapharsen and a bismuth compound. Eight hours after the first mapharsen injection he experienced severe headache, paresthesias, chilly sensations and anorexia. Four hours after the third mapharsen injection he felt faint and nauseated and again experienced paresthesias, severe headache and chills and developed conjunctivitis.

Physical examination on admission to the hospital revealed that the patient was moderately ill and slightly icteric with a temperature of 100.8 F and a generalized erythema. There was some tenderness of the muscles and pain on flexion of the joints. The liver and spleen were not palpable.

Examination of the urine revealed a 2 plus test for albumin and a positive test for bile. The centrifuged sediment contained 2 to 6 renal epithelial cells per high power field, 0 to 2 epithelial cell casts and occasional leukocytes, leukocyte casts and coarsely granular casts. The red blood cell count was 3,800,000 per cubic millimeter, with 115 Gm of hemoglobin per hundred cubic centimeters. The white blood cell count was 10,000 per cubic millimeter, with 69 per cent polymorphonuclear leukocytes. The stools were clay colored and negative for bile and urobilinogen. The qualitative urine urobilinogen test was also negative. The blood nonprotein nitrogen was 214 mg per hundred cubic centimeters and the icterus index 57. The van den Bergh test showed an immediate direct reaction; the cephalin cholesterol test was negative and the prothrombin time was 22 seconds, normal control 21 seconds. The red cell fragility test showed beginning hemolysis at 0.36 per cent. There was no sickling.

Despite the clinical and laboratory evidence of obstructive jaundice and because of the history of recent therapy with

M. and Gutman, A. B. Postarsphenamine Jaundice Apparently Due to Obstruction of Intrahepatic Biliary Tract. *J. A. M. A.* 115: 263 (July 27) 1940.

arsenicals, the patient was placed under observation for four and a half weeks. During this time he complained of anorexia and occasional abdominal cramps. Six days after the last mapharsen injection his temperature fell to normal and remained so thereafter. The urine albumin, casts and cells cleared in two weeks. The liver and spleen were at no time palpable. A gastrointestinal series was negative and scout films of the abdomen failed to reveal calcific densities in the region of the gallbladder. A roentgenogram of the chest was negative.

The icterus index rose gradually to 136. The stools were either yellow or completely clay colored with either a negative or a faint trace reaction when tested for bile and urobilinogen. The urine urobilinogen remained persistently negative. One month after admission the serum protein was 8 per cent, with 49 per cent albumin and 31 per cent globulin. The hippuric acid excretion was normal (374 Gm). The blood cholesterol was 300 mg per hundred cubic centimeters. The glucose tolerance test was normal, at fasting level being 90 mg per hundred cubic centimeters at one-half hour 160 mg per hundred cubic centimeters, at one hour 146 mg per hundred cubic centimeters and at three hours 68 mg per hundred cubic centimeters.

Because of the persistence of the signs of obstructive jaundice, it was felt that an exploratory laparotomy was indicated. This was done thirty-three days after admission. No evidence of extrahepatic biliary obstruction was found. The liver was smooth green and of normal size. The common duct was explored with negative results, and a biopsy of the liver was taken.

Following operation the daily output of bile varied from 50 to 260 cc. Cholangiograms taken at this time by injection of dye through the tube revealed filling of the bile duct radicles. The icterus index gradually fell over a period of two months to 25. At the same time urobilinogen appeared in the urine. The patient's only complaint was itching which was quite severe and lasted for three weeks during the time the jaundice was clearing. The anemia and anorexia receded during parenteral liver therapy and high vitamin and iron intake by mouth.

Two months after admission the glucose tolerance test showed a fasting level of 74 mg per hundred cubic centimeters, one half hour 76 mg per hundred cubic centimeters, one hour 80 mg per hundred cubic centimeters, two hours 78 mg per hundred cubic centimeters, three hours 78 mg per hundred cubic centimeters. This was repeated five days later with essentially similar results. The patient was then given 50 Gm of glucose intravenously with the following results: fasting level 71 mg per hundred cubic centimeters, one half hour 154 mg per hundred cubic centimeters, one hour 79 mg per hundred cubic centimeters, one and one half hours 74 mg per hundred cubic centimeters, two hours 71 mg per hundred cubic centimeters, three hours 71 mg per hundred cubic centimeters. The galactose tolerance test revealed 0.8 per cent reducing substance in the one hour specimen and none in the remaining four hourly specimens.

The blood calcium on two occasions was 8.2 per cent and 7.8 per cent respectively. The stools were voluminous and greasy but were gray brown, were positive for bile and contained numerous fat globules when stained with sudan III or scarlet red. A gastrointestinal series revealed a normal mucosal pattern in the small intestine.

The jaundice gradually cleared over a period of four and a half months at which time the icterus index was 9. The glucose tolerance curve had returned to normal and the stools contained considerably less fat than previously observed although abnormal amounts were still present. The excretion of bromsulphalein at this time showed a pronounced delay, there being 90 per cent retention at five minutes and 75 per cent at thirty minutes. Other liver function tests which do not depend on biliary excretion remained normal. Examination of the duodenal contents using the method of Lueders² revealed the presence of trypsin and lipase qualitatively. The patient had gained weight and felt quite well.

The pathologic examination of the liver biopsy by one of us (E D F) revealed that the biopsy specimen had a distinct green color and the cut surface showed numerous punctate areas of dark green pigment scattered throughout the parenchyma.

Microscopic examination revealed: 1 There was increased cellularity of the portal areas due to infiltration of lymphocytes and a few polymorphonuclear leukocytes and eosinophils. There was no dilatation or proliferation of the bile ducts. 2 Numerous scattered focal areas of swollen liver cells were seen around the central veins and in the midzonal regions but not around the portal areas. The most striking feature in these areas was the distention and plugging of the canaliculi with bile thrombi. The Kupffer cells in the region of the efferent vein were loaded with bile pigment. 3 Necrosis and inflammatory changes in the parenchyma characteristic of hepatitis were absent, as shown in the photomicrograph.

The diagnosis was pericholangitis and cholangiolitis.

Biopsy of the liver. The rounded dark areas are bile thrombi. There is much inspissated bile in the region of the central vein (I). The liver cells are enlarged except around the portal areas but do not appear degenerated. The portal area (II) is infiltrated with lymphocytes. The small bile duct (III) is not distended and contains no bile.

COMMENT

That this patient presented the syndrome of obstructive jaundice is evidenced by the presence of a steadily deepening icterus with clay colored stools, no enlargement of the liver and/or spleen, negative urine urobilinogen, immediate direct van den Bergh reaction, elevated serum cholesterol, negative cephalin cholesterol test, no increase in the prothrombin time, adequate excretion of hippuric acid and a normal serum protein partition. However, after the laparotomy it became evident that this case was an example of postarsenical jaundice apparently due to the intrahepatic obstruction described by Hanger and Gutman. The prolonged clinical course, the onset with fever and erythema following the third injection of an arsenical and the histopathology of the liver biopsy specimen were identical with the syndrome observed by these authors.

Although this syndrome is a comparatively uncommon reaction to arsenicals, the fact that it can occur makes it important in the differential diagnosis of the patient with obstructive jaundice who gives a history of recent treatment with arsenic.

Our attention was drawn to the spruelike syndrome when we found, during the period of gradual disappearance of the jaundice, that a previously normal glucose tolerance curve became flat. That the appearance of this abnormality was due to faulty absorption by the intestinal tract became evident when a normal intravenous glucose curve was demonstrated.

² Lueder, C. W. Quantitative Estimation of Enzyme Concentration in Duodenal Fluids. A Practical Clinical Method. *Am. J. Digest. Dis. & Nutrition* 2: 224 (June) 1935.

The probability that a deficiency in the absorptive mechanism existed in the intestinal tract was further emphasized by the appearance of voluminous greasy stools containing large amounts of fat during the time that bile was reaching the intestine and by the low blood calcium. The demonstration of the presence of trypsin and lipase in the duodenal contents suggests that the steatorrhea was not due to a deficiency of pancreatic enzymes. The absence of anemia and glossitis and the other B complex and fat soluble vitamin deficiencies at this time can be attributed to the fact that the patient received liver extract and vitamin K parenterally as well as vitamin supplements by mouth during the month following operation.

Although the syndrome resembling sprue has not been previously described in cases of postarsenical jaundice due to intrahepatic obstruction, it is of interest to note that Farber³ has observed a similar hepatic lesion in some cases of steatorrhea in infants. The possible etiologic relationship must await further observations.

SUMMARY

A case of jaundice following the injection of mapharsen exhibited the clinical and laboratory data consistent with the diagnosis of extrahepatic biliary obstruction. No extrahepatic obstruction was found at operation, but examination of the liver biopsy revealed pronounced inspissation of bile in the bile canaliculi.

During the course of the disease the patient developed a syndrome which resembled sprue in many respects.

THE DOCTOR LOOKS AT HIS INVESTMENTS

WALTER J. J. SMITH

BALTIMORE

INTRODUCTION

The author, Mr. Walter J. J. Smith, is a graduate in the field of commerce of New York University, with the degree of Master of Commerce. He was a member of the editorial staff of the *Financial World* from 1937 to 1944 and since that time has been supervisor of accounts for *Market Trends*.

An outstanding characteristic of the investment counsel field has always been the youthfulness of the "old men" supervising investment portfolios. But in this field—as in all others—the war has brought changes. The "old men" of finance are now in the armed forces and the portfolios they formerly supervised have either been placed in the hands of other counselors already overburdened or else left to drift until the day when manpower mobilization becomes manpower demobilization. In either event a disservice, not a service, is being performed and the financial consequences of the action can only be imagined. We are assuming in this article that the doctor's portfolio is in the latter group. Since there is no substitute for competent and continuous investment counsel supervision, the following routine is not offered as a permanent "cure-all" for investment problems. Rather, the procedure is offered as a simple and satisfactory temporary method of supervision that avoids most of the investment pitfalls and makes minimum demands on the doctor's time.

In the light of the exhausting schedule being maintained by medical men in general, it would probably be no oversimplification of this investment problem to say that the physician should seek the freedom from worry and supervision achieved through the purchase

of U. S. government bonds. But the average doctor will take one look at the return on such an investment and conclude that he can stand a little less security and a little more income. The result must be a compromise investment.

Now the question immediately arises as to how far down the investment quality scale he should go. In my opinion no doctor considering the purchase of bonds and preferred stocks has the financial or moral right to go under the type of security now included in the medium grade group. Profitable operations in speculative securities demand the individual's maximum attention, and competent medical practice also demands the doctor's full time and interest. Experience has proved time and time again that the professional man whose portfolio continues to be heavily weighted with speculative issues will inevitably become a less competent man in his profession. The reason is simply that no man can serve two masters.

At the present time, issues in this medium grade group—which is constantly being adjusted to the rate of "pure interest"—yield between 4 and 6 per cent in the case of bonds and $5\frac{1}{4}$ to $6\frac{1}{4}$ in the case of preferreds. Note that the reference is not to any conventional system of alphabetical rating but rather to the market's own rating of the worth of the securities in the light of existing money market conditions. For the time being, therefore, purchases in this section of the security list should be limited to bonds and preferred stocks qualifying in this class. By the same token, such securities should be sold whenever they leave the medium grade group either on the top or on the low side as a result of yielding less than or more than the limits set up. If this routine is adopted, it will be possible to secure yields more than twice as large as those obtainable on long term taxable Treasury's with only a nominal increase in risk, the reason being simply that a definite plan of "merchandising" the securities is being followed. It is also apparent that the supervisory detail is reduced to a minimum because of the arbitrary procedure. Last but by no means least in these days of heavy taxation, the capital gains and losses over a period of time will tend to cancel out.

Even though this type of security will represent at least the major part of a doctor's portfolio, it is admitted that a well balanced list should also include common stocks. Unfortunately, the relatively simple yardsticks used above are not applicable here. Although brief reference to the financial publications will show an endless array of forecasting mediums, the more successful investment managers base their purchases and sales on broad economic and psychologic factors. At least one service—looking inside the market itself for an indication of future trends—has reduced the investing public's anxiety or optimism (the prime moving factor) to a simple ratio and uses it as a forecasting tool. While the advantages of this method are obvious, most people have neither the time nor the inclination to engage in the dreary task of adding up long series of figures in order to arrive at the necessary ratios. But the general principles of (1) When to buy or sell and (2) What to buy or sell can be employed with profit.

For example, the Dow-Jones averages are the fever chart of business. Reading this business thermometer differs in no respect from any other chart with which the doctor is familiar. Here the danger zone constitutes points where major changes in investment policy must be effected. The years 1932, 1938 and 1942 were points of primary interest to the investor concerned.

³ Farber, S. Medical Progress. Pancreatic Insufficiency and the Celiac Syndrome. *New England J. Med.* 229: 623 (Oct. 21) 1943 (Oct. 28) 1943.

only with adjusting his portfolio to the long range swings in the market. Stated another way, these major turning points were of interest primarily to those anxious to catch most of the bull market rise but side-step entirely the bear market declines. No close and continuous watching of market trends was necessary for such trading action. Although, in matters of this sort, long experience with the charts is of paramount importance if consistent success is to be secured, a victory model short-cut can be offered instead. There are four points to be remembered, and, if they can be kept clearly in mind, most of the investment pitfalls will be avoided. They are that 1 Bull markets tend to run for an average of almost two years and increase the general level of security prices about 65 per cent. 2 Bear markets run almost one year on the average and show price reductions averaging 40 per cent. 3 Since these are only average figures and any specific bull or bear market may run longer or shorter and increase more or less than the figures shown, limit the potential loss in any security to 20 per cent. A penalty of this size for a poor guess is not pleasant medicine, but it does have the virtue of preventing a possible 40 or 50 per cent loss. 4 Note the trend in low grade securities against the high grade issues and the kind of securities that are the current favorites.

The first two points will enable the busy professional man to determine in a general way just where the market stands with respect to the "typical" bull or bear market both in duration and in extent of increase or decrease and gauge his action accordingly. Obviously, considerably more caution must be exercised when buying into a bull market that has been boiling along for three or four years and has increased the general price level 70 per cent than when considering similar action in the same market if it has been moving along for only one year or even less and scored advances of only 10 per cent. Remember that the only good buying spot is the beginning of a bull market. As prices move up, profit possibilities become less and the risks of a loss correspondingly greater. In other words, proceed with increasing caution when buying into the later stages of a bull market and be prepared to move out in a hurry if the tide starts to run out, particularly if the "average" performance has already been realized and point 4 shows that speculative issues have dominated the market for a long time not only from the point of view of activity but also in the light of price gains registered.

Of course, the reverse comments apply in the case of a bear market. Never buy into a bear market that has just started irrespective of the quality of the security being offered for sale. If you will check the records, you will find that the good stocks crashed in 1929 and 1937 along with the poor ones and it was no consolation to the holders of the good stocks to know that they did not go down as much. The fact was they could have been purchased at a better price later in the bear market. The advantage of point 3 is self evident. Point 4 is intended to be a quality test of the market. Admittedly conclusions based on the exact method suggested can only be approximate at best. The reduction of this figure to a calculated ratio is more desirable, but remember that such computations are time consuming and "free time" is something a medical man does not have. I am attempting to show in a general way simple guideposts for temporary use until the portfolios in question can again be placed under professional supervision.

After the major question of when to buy is determined, the secondary question of what to buy arises. Early in a bull market the quality of purchases can be relatively lower, but the standards should be raised as the market gets into the "average" ranges indicated under the first two points. Also each issue should be selected with a view toward proper diversification within the portfolio, since an undue concentration of funds in any single issue is not sound. Obviously there is no cut and dried answer to that problem, since it will depend on the particular phase of the market at which the question comes up and also on the present composition of the portfolio in question. If the problem is one of what to sell, the answer is not difficult. The practical attack is to begin with the most speculative equities held and work up toward the more conservative securities, the extent of the action depending on the severity of the indicated decline. It must be remembered that there are times when the most desirable investment to hold is cash as well as times when one should be almost fully invested.

In a mechanism as complex as the security market and almost impossible to subject to laboratory analysis no foolproof rules can be found. However, it is hoped that the guideposts mentioned here will enable "my doctor" to muddle through the constantly shifting financial and economic sands with at least average success until his "old man" of finance returns.

Council on Pharmacy and Chemistry and Council on Industrial Health

The Council on Pharmacy and Chemistry and the Council on Industrial Health have authorized publication of the following report

AUSTIN SMITH, M.D., Secretary

C. M. PETERSON, M.D., Secretary
COUNCIL ON INDUSTRIAL HEALTH

THE USE OF VACCINES FOR THE COMMON COLD

Status Report

The symptom complex usually termed the common cold is a frequently recurring source of distress and disability to most residents of temperate climates, and it is the cause of much industrial absenteeism and economic waste. In recent years so-called vaccination is the method which has received the greatest amount of study as a possible means of preventing or controlling the ravages of this condition. If any available vaccine has demonstrable value for the prevention of the common cold or aids in its control it would be a boon of tremendous value and the method should be more widely utilized in practice, if on the contrary, the vaccines which are available are not of value in any of these respects then many members of the medical profession are being misinformed and the public is spending large sums uselessly.

The evaluation of the evidence for any prophylactic measure against the common cold is complicated by many factors which do not lend themselves readily to controlled investigation. All colds may not and probably do not have the same virus or bacterial causation; the frequency and symptomatology of colds in the community vary widely from year to year; the common cold is so mild that its victims rarely come under the direct observation of a physician during the period of invalidity; there are great differences in how people describe the severity and duration of their own colds and consequently most reports on colds are based on unreliable subjective accounts.

Scientific evidence must exclude everything of the so called 'testimonial type'. Any one person's history of 'colds' over a period of years will vary too much to allow the acceptance of such individual testimony on the results of vaccine prophylaxis. It is only through the use of a uniform type of vaccine for large numbers of persons with equally large numbers of controls over a long period of time that acceptable proof of efficacy can be obtained. These criteria applied to published reports eliminate all but a few from the necessity for serious scientific consideration.

Vaccines designed to reduce the incidence or severity of the common cold have been administered hypodermically, by the swallowing of capsules (so called oral vaccine) and more recently by local application to the mucosa of the upper respiratory tract by means of sprays. The constituents of the vaccines used have varied widely but most have been made up of heat or chemically killed organisms obtained originally by culture from the upper respiratory tract and combined in various proportions. The lack of agreement on the most desirable route of administration and the even greater lack of agreement on the types and proportions of organisms to include in the vaccines and on the methods of killing and preparing them are in themselves arguments against any scientific standing for this procedure. A greater measure of uniformity on these procedures would be necessary to remove a procedure of this nature from the realm of pure experiment.

ORAL VACCINES

A large number of articles in the medical literature¹ indicate the writers' belief that vaccines of various types may have some value for decreasing the incidence of colds or for reducing their severity or the incidence of complications. Most of the recent studies of a controlled nature have been with oral vaccines of which Entoral Lilly, Catarrhal Oravax-Merrill and the Cutter vaccines are highly publicized examples. Entoral was declared unacceptable for inclusion in New and Nonofficial Remedies in a report of the Council on Pharmacy and Chemistry published in 1937, - Catarrhal Oravax, while not considered in that report was discussed in a Current Comment in THE JOURNAL² in which it was pointed out that the evidence for its value was equally unacceptable. Since that time Stafford,³ the Forgraves⁴ and Murat⁵ have published controlled reports on oral vaccines for the common cold in which the results were believed to be predominantly favorable. Stafford's report is based on a group of 338 students, one half of whom were given an enteric coated capsule each containing 50 million killed organisms including pneumococci types I, II and III Neisseria

catarrhalis, Hemophilus influenzae, Klebsiella pneumoniae, streptococci and staphylococci, and the other half a placebo containing starch and sucrose. Comparisons of the incidence of 'severe colds' was used as the index of effectiveness. Except for one week of the eight week period of observation, the incidence of 'severe colds' was less among the group receiving oral vaccine than among the controls. The number of 'mild colds' in the two groups did not differ materially, and the significance of the difference in severe colds was apparently not subjected to statistical analysis. The Forgraves, using the same type of oral vaccine, studied a group of 40 industrial workers divided into two groups; they record a reduction in the average number of colds between seasons of some 4.85 to 1.45 in the experimental group and from 4.2 to 3.9 in the controls. In numbers and period of observation this study appears to be deficient as a report on which adequate conclusions can be based. Murat divided 1,273 subjects into two groups, alternate individuals being given tablets containing 'soluble antigenic derivative of the bacteria commonly found in the respiratory tract,' while the others were given similar tablets containing an innocuous substance. This author considered that there was a difference in susceptibility to colds in favor of those taking the vaccine; there was a loss of time in 63 per cent of those taking the vaccine as against that of 86 per cent of those taking the placebo, although how this was determined was not stated.

Most of the other 'controlled studies of oral vaccination against colds either fail to demonstrate any usefulness or are distinctly inconclusive. A particularly careful investigation of oral cold vaccines was performed by Siegel and his colleagues.⁷ A commercial product composed of mixed heat killed bacteria commonly found in the respiratory tract was employed. Single capsules were taken daily for the first fourteen days and twice weekly thereafter. Two hundred and fifty-three persons were involved in the study, divided into almost equal test and control groups. The number of colds in the two groups was exactly equal. The average duration of symptoms experienced by the group taking the vaccine was 10.5 days per cold as compared with 9.7 days for the control group. The number of days of absence during the test period on account of respiratory illness varied from 0 to 43 but there was no striking difference in this respect between the test and control groups. These investigators concluded that the vaccine when given according to the manufacturer's directions did not have any influence on either the incidence or the severity of the common cold. Similarly, they could not observe any effect as a result of this treatment on the secondary complications frequently associated with the common cold. Other negative controlled studies, often involving several types of vaccination but all of them including one or more oral vaccines, have been reported by Diehl and his colleagues⁸ and by McGee and his colleagues.⁹ Toomey¹⁰ while not presenting any studies based on controlled observations on human beings discussed the logic on which the immunologic basis for this form of prophylaxis rests and concluded that the case for oral vaccination against colds has not yet been made.

PARENTERAL VACCINATION

Extensive attempts to employ other routes of administration have also been made. The most important of these is by hypodermic injection including intramuscular, subcutaneous and intradermal. Although it has not received much attention in this country, the report by Bashford¹¹ based on observations in employees in the English Post Office System, are, because of the duration and numbers involved, particularly impressive. That study was made over a three year period by injection of a mixed bacterial vaccine. The colds in the injected and in an adequate control group were recorded. The average absence for sickness from colds among those receiving the vaccine during the first year of the experiment was less by half of one day than that of the noninoculated group. During the second

year the average absence due to such disorders among the inoculated was 0.1 day higher than that in the noninoculated group, and during the third year was 0.2 day higher than that in the controls. With a symptom complex of this type, such infinitesimal variations must obviously be considered to be without significance. Houser¹² employed a mixed bacterial vaccine by hypodermic injection in students at the University of Pennsylvania over a four year period. He concluded that the prophylactic vaccination was followed by a lessened severity and duration of the 'disease' but that there was little evidence that colds were prevented by this type of therapy. At the University of Michigan, however, the Hausers¹³ studied comparative groups given a vaccine or placebo subcutaneously and intradermally. The results were not conclusive and there was little definite difference between the groups. Similarly Stanley,¹⁴ Diehl and his colleagues¹⁵ and others¹⁶ failed to find clearcut evidence of the value of bacterial vaccine for colds or their complications.

OTHER TYPES OF VACCINATION

The work of Besredka and those who have succeeded him has suggested that immunity to certain diseases can be built up in local tissues in excess of that circulating in the body as a whole. In pursuance of the implications of this suggestion Walsh¹⁷ in a series of articles has presented experimental and clinical evidence on the use of a mixed bacterial vaccine applied as a spray to the nasal mucous membrane with the purpose of assisting the prophylaxis of the common cold. Walsh's observations have been on the whole encouraging to the use of this procedure, and his investigations have been more conservatively presented than those of many other proponents of new procedures. Nevertheless Cowan and Diehl,¹⁸ in a controlled study in human beings of this method of vaccination have failed to obtain any evidence of its value or to confirm its clinical usefulness.

Other reports giving mainly negative results with the use of some type of vaccine have appeared (e. g. Schreuder¹⁹), but usually they have not been based on a large enough number of persons or observations over a long enough period of time to be considered decisive.

CONCLUSIONS

Vaccines prepared from a variety of bacteria commonly found in the respiratory tract have been prepared and combined in sundry ways and have been administered by various routes with the purpose of preventing colds decreasing their incidence, ameliorating their symptoms, shortening their duration or decreasing their complications, or all of these combined. These objectives are all highly desirable. Unfortunately the evidence of individual case reports does not have any value in a disorder such as 'the common cold,' which probably covers a multiplicity of infections which are only symptomatically related. The only evidence which has scientific value is that which can be obtained by carefully controlled studies by qualified observers on large numbers of persons over a sufficiently long period of time to overcome the natural fluctuations in the major features of this symptom complex. Decisive evidence of the value of any vaccine is not forthcoming, and the weight of careful studies clearly indicates that none of the vaccines now available when administered by the routes advised have proved value. Vaccines for colds cannot be recommended for routine administration to industrial groups or to individuals. At present any attempt to

prevent colds by the use of vaccines must be recognized as purely experimental and any proposal to administer such a vaccine, if given at all, should take this into consideration. As in all measures of a purely experimental nature the uncontrolled use of any cold vaccine now available should be discouraged. Industrial physicians are under particular obligation to employ cold vaccines if at all, only under the most rigidly controlled conditions and to report their results so that useless preparations can be promptly eliminated and further progress made.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to *New and Nonofficial Remedies*. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary

CONTRACEPTIVE CAPSULES AND SUPPOSITORIES (See chapter on Contraceptives, New and Nonofficial Remedies 1944, p. 339)

Actions and Uses—Capsules and suppositories provide a convenient method for introducing obstructive and spermicidal material into the vagina with the advantage of freedom from the need of apparatus. The solid material introduced must be converted to a jelly or liquid form in order to cover the requisite area, hence prompt liquefaction is important. For some suppositories this results from a melting point below the temperature of the body. For others the active material is enclosed in a gelatinous shell which melts or opens when exposed to body temperature and moisture. The time required should be under ten minutes, and the users should be instructed to allow this time to elapse before intercourse. A douche should not be taken within six hours after ejaculation.

To insure further protection physicians may advise the concurrent use of an occlusive device such as a diaphragm (concerning which see general statement).

PERNOX, INC., NEW YORK

Pernox Vaginal Capsules—A soft gelatin capsule containing a low melting mass prepared from the formula

Ricinoleic acid	0.045 Gm
Propylene glycol monostearate	1.830 Gm
Woolfat fraction	2.200 Gm
Wetting agent	0.045 Gm
Propylene glycol	0.183 Gm
Tragacanth	0.214 Gm

Actions and Uses—See preceding article, Contraceptive Vaginal Capsules.

Dosage—One capsule containing 4.5 Gm

PENICILLIN (See THE JOURNAL, Oct 7, 1944, p. 367)

The following products have been accepted

PARKER, DAVIS & CO., DETROIT

Penicillin (Sodium Salt) Vials or ampuls each containing 100,000 Oxford units

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Penicillin (Sodium Salt) Ampuls containing 100,000 Oxford units

E. R. SQUIBB & SONS, NEW YORK

Penicillin Sodium Packages containing 100,000 Oxford units

CITRATED NORMAL HUMAN PLASMA (See New and Nonofficial Remedies, 1944, p. 533)

The following additional dosage form has been accepted

HYLAND LABORATORIES, LOS ANGELES

Normal Human Plasma 50 cc and 500 cc bottles. Containing an amount (preserved with phenylmercuric borate 1:25,000) to yield 50 cc of restored plasma packaged with a 50 cc bottle of distilled water as a diluent (preserved with citric acid 0.1 per cent).

AMPHETAMINE SULFATE (See New and Nonofficial Remedies 1944, p. 265)

The following additional dosage form has been accepted

SMITH KLINE AND FRENCH LABORATORIES, PHILADELPHIA

Benzedrine Sulfate Elixir 177 cc bottles. Each 3.69 cc contains racemic amphetamine sulfate 25 mg and alcohol 10 per cent.

SATURDAY DECEMBER 2 1944

HERPES ZOSTER VIRUS

In 1925 Kundratitz¹ inoculated the scarified skin surfaces of 3 infants with the clear contents of herpes zoster vesicles. After eleven days 2 of the infants developed several clear vesicles with slightly reddened peripheries. In subsequent tests 4 typical cases of thoracic herpes zoster produced typical local vesiculation of the skins of several children, all of them under 5 years of age. The lesions thus produced corresponded closely with the inoculatory vesicles of chickenpox previously described by Kling². In 1921 Lipschutz³ described intranuclear acidophilic inclusion bodies in the lesions of herpes zoster apparently identical with the inclusion bodies previously described in the cutaneous lesions of chickenpox.⁴

In spite of repeated trial, herpes zoster virus has never been successfully inoculated in series into any laboratory animal. In attempts to find another feasible research technic Goodpasture and his associates⁵ of Vanderbilt University grafted samples of normal human skin on the chorioallantois of chick embryos. They found that such grafts are rapidly vascularized and that they survive for at least ten days, a period sufficiently long for inoculation tests. Such grafts were susceptible to inoculation with the viruses of herpes simplex, variola and vaccinia but refractory to the virus of chickenpox.

Such grafts have now been used in a study of the causative agent of herpes zoster. To do this a Thiersch graft from the thigh of an adult surgical patient was cut into 1 cm squares. On each square there was placed a drop of undiluted fluid from the vesicles of herpes zoster from a second individual. With the aspiration needle (size 27) multiple punctures were made through the drop into the surface of the graft. One hour later each graft was placed on the chorioallantois of a 9 day

old chick embryo. All grafts adhered successfully. The grafted eggs were then incubated for periods ranging from four to eight days, at the end of which period the grafts with adherent chorioallantois were fixed in Zenker's solution.

Microscopic study showed that the grafts had developed small foci of infection by the fourth day at the sites of the multiple needle punctures, increasing by the eighth day to relatively large pustular foci. The earlier lesions consisted of small groups of hyperplastic epithelial cells whose swollen nuclei contained characteristic acidophilic inclusion bodies. In the later lesions the epithelial cells were separated from one another by inflammatory fluid and cellular exudate consisting largely of chick leukocytes. In none of the lesions had sufficient fluid accumulated to cause gross vesiculation. There was no evidence of infection of the underlying chick cells.

Experimental herpes zoster lesions in grafted human skin serve to throw light on the controversial question of the pathogenesis of the herpes zoster eruption. Many clinicians⁶ have so overemphasized the presumptive role of the neurovascular mechanism as to imply an absence of the virus in the skin lesion. Goodpasture believes that the failure of the experimental lesions in his skin grafts to develop completely as vesicles merely indicates the importance of neurovascular connections for the formation of the abundant serous exudate in the human eruption. Of greater hygienic interest is his finding of the apparent nonidentity of the herpes and chickenpox viruses, which identity is suggested by a large body of clinical evidence. Whether or not the nonidentity is due to specificity differences or to differences in virulence has not yet been determined.

DRUGS AND THE DOCTOR

Those Americans who are inclined to find fault with the development of medical affairs in this country and who seek constantly to disparage what is being done in comparison with European models will find food for thought in an editorial just published in the *British Medical Journal*¹ entitled "Drugs and the Doctor." That editorial points out that a noticeable hiatus in the White Paper, which is a plan for medicine in Great Britain, is the failure to consider the bearing of a national health service on the supply of drugs and apparatus. The *British Medical Journal* emphasizes that the use of proprietary remedies has increased since the introduction of National Health Insurance and that the effect of this has been harmful to personal and social health. After a consideration of British legislation in relation to the marketing of proprietary remedies, the editorial asserts: "No medical service is likely to be

a success unless it leaves the individual practitioner considerable freedom in prescribing."

Our British colleagues render a great tribute to the work of the Council on Pharmacy and Chemistry of the American Medical Association in the following paragraph taken from the editorial

The difficulty is that no one has a vested interest in sane pharmacotherapeutics, and therefore active steps must be taken by the profession or the community to redress the balance. The individual doctor or patient must be supplied with unbiased information. The Americans manage these things better than we do, and a recent account of the Council on Pharmacy and Chemistry of the American Medical Association deserves serious study in this country. The Council has no legal powers, but most readers will agree with the claim that no single body in modern times has brought about so much change in the practice of therapeutics. The Council derives its influence largely from the important group of medical journals published by the American Medical Association, whose pages are closed to advertisements or names of preparations which are not approved by the Council. Its success has been such that it has become a model for the Council on Physical Therapy, the Council on Foods and Nutrition, and the Council on Dental Therapeutics. It consists of 17 members chiefly professors of medicine and pharmacology in the American medical schools, who work without remuneration but with a whole time medical secretary. The Council does not initiate clinical trials, and as a general rule the manufacturer must submit the evidence for therapeutic or other claims, which is then reviewed by the members of the Council, together with advertising material and other pertinent data. All the Council's actions, whether of acceptance, rejection or omission, are published in the *Journal of the American Medical Association*, and later in the book *New and Nonofficial Remedies* or in the annual reprints of the reports of the Council. The Council's work has been of immense educative value to the members of the American Medical Association, for, however keen an observer the individual clinician may be, he cannot research on all diseases all the time. It has overcome the kind of difficulty which occurs when new and potentially dangerous drugs, such as thiouracil, are introduced to the profession. We agree with a recent letter in our own columns to the effect that once these drugs are put on the market there can be no arbitrary selection of those doctors who use them. At the same time there is need for a mechanism for supplying information about them and for seeing that they are properly labelled. It is above all in the practice of correct nomenclature that the Council on Pharmacy and Chemistry has done most good, and it must be confessed that the advertising pages of medical journals and the demonstration stands at medical exhibitions in Great Britain compare unfavorably with their American counterparts.

This statement is particularly timely when some of the editors and business managers of medical periodicals in the United States have suggested that the Council on Pharmacy and Chemistry relax its standards in relation to the acceptance of claims for drugs and particularly in the matter of nomenclature. The British observe that it is above all in the practice of correct nomenclature that the Council on Pharmacy and Chemistry has done the most good, and they admit frankly that the advertising pages of medical journals and the demonstration stands at medical exhibits in Great Britain compare unfavorably with their American counterparts.

In a recent session the Board of Trustees of the American Medical Association reaffirmed its full support of the standards of the Councils on Pharmacy and Chemistry, Food and Nutrition and Physical Medicine. In this stand the Board of Trustees and the individual Councils merit the fullest support of the American medical profession.

RATE OF FLUID ADMINISTRATION IN SHOCK

Although the loss of the cellular elements of the blood has been emphasized¹ as an important factor in shock, a disturbance of the effective relationship between blood volume and vascular space has a significant role in its causation. Restoration of fluid to the blood vessels therefore becomes an effective treatment if begun before secondary changes occur. Isotonic solutions of salts are essentially ineffective because of the rapid disappearance from the circulation. For this reason various substances with large molecular weights were used as colloidal solutions because the nondiffusible micelles exert enough osmotic pressure to retain fluid within the blood vessels.

The method of administering therapeutic agents for combating shock is emphasized in recent observations on experimental shock by Swingle and Kleinberg.² Wound shock involving severe muscle trauma with external and internal hemorrhage was produced in deeply anesthetized dogs. Under reproducible experimental conditions fatal shock was observed in 90 per cent of a large number of untreated animals, a drop in arterial pressure and a decrease in plasma volume characterized the syndrome. During treatment with saline solution, plasma or gelatin, single massive transfusion was compared to the same volume divided into five doses given at once and at one, two, four and seven hours after the injury. Intermittent administration of plasma was highly efficacious in preventing shock, whereas a single large infusion given within ten minutes of the injury exerted little effect in this respect. Gelatin solution given intermittently was likewise effective but to a lesser degree than plasma. Even isotonic solution of sodium chloride administered in small amounts over the extended period showed an alleviating effect, though in turn somewhat less than that of gelatin. In a single dose the salt solution was essentially ineffective.

Under the conditions of these experiments, definite improvement in the treatment of shock results when massive single transfusions of fluid are replaced by intermittent administration of the same amount. The factor of rate of fluid administration seems worthy of attention in the treatment of shock in human patients.

Current Comment

"COLD VACCINES"

In this issue of *THE JOURNAL* (page 895) appears a report sponsored jointly by the Council on Pharmacy and Chemistry and the Council on Industrial Health of the American Medical Association dealing with the use of so-called vaccines for the prevention of the common cold. The report points out that there is no uniformity in the types of vaccines employed, in their mode of administration or in the method of evaluating the results. None of the vaccines now available has proved value, none can be recommended for industrial groups or for individuals. In spite of the overwhelming evidence on this subject, some pharmaceutical firms continue to engage actively in the promotion and sale of various "vaccines" for the prevention of colds. This constitutes an irresponsible attitude toward the public and the medical profession, no better than most of the claims regarding the alleged benefit to colds from vitamins and proprietary nostrums. The air waves and the drug counters are crowded with so-called preventives or cures of these types, which do not serve any recognizable purpose other than to lighten the public purse.

THE GILES TWINS OF THE A A F

If twin pairs entered the Army by mere chance one would expect them to appear once in 16 384 Army Register entries, whereas the actual frequency of their listing is over thirteen times as often.¹ The story of one conspicuous pair of army twins establishes again the extent to which identical twins resemble each other. These brothers carry between them five stars and demonstrate in their military history a parallelism which is most unusual. Lieutenant General Barney McK Giles entered the Army as a private, first class, in the Signal Corps in 1917, was commissioned a second lieutenant in the following year, was honorably discharged in 1920 with the rank of first lieutenant and was reappointed to that rank a few months later. He became a major in 1939 two years later a lieutenant colonel and in the spring of 1942 was advanced to the rank of brigadier general and in the fall of that year to major general. He was promoted to lieutenant general a little later and became chief of staff of the Army Air Forces only a few months later. Major General Benjamin F. Giles entered the Army in 1917 as a second lieutenant of infantry, was honorably discharged in 1919 with the rank of first lieutenant, was recommissioned a second lieutenant in 1920 and became a major in 1930 and a temporary lieutenant colonel in 1939. In 1942 he was advanced to the rank of brigadier general and recently to that of major general. Both officers began their military careers in World War I at age 25, neither

went to West Point and they entered the Army at different times but both quickly transferred to aviation and continued in that service. Both were advanced to higher rank from near the bottom of the preceding grade. This unusual military history again demonstrates that identical twins from the genetic standpoint are the same individual in two bodies.

MENTAL DISORDERS AND POPULATION DENSITY

At the Boston Armed Forces Induction Station a comparison was made between the rejection rates for the major mental disorders in selectees examined and the population densities of the communities from which they came.¹ Allowance was made for the socioeconomic factors and national origins, both of which influence the rate of mental disease. The highest rates of mental disorders occurred at the two extremes of population density—that for mental deficiency and psychoneurosis appeared in the semirural areas (500 per square mile) and for chronic alcoholism and psychopathic personality in a large city—Boston. Only chronic alcoholism was correlated with population density at every level. The study included communities that had the highest rates of mental disorders and those that had the lowest. Of the thirteen communities with extremely high rates, eight were in the extreme density bracket (over 20,000 people per square mile), whereas of the thirteen communities with low rates not one was in either extreme density bracket (under 500 or over 20,000 population density). Hyde and Kingsley find it not surprising that rural areas and the great city have similar rates of mental disorders. For both types of community, they say, have many unfavorable features. Only between these two extremes is there a mean that satisfies most fully the aspirations of modern life. In the community of middle size there are those advantages of interest, stimulation, excitement, of easy accessibility of recreation facilities, best opportunities for modern conveniences, without the loss of readily available rural advantages of open fields, woods and strong family life. The most adequate people, as judged by their adaptation to modern life, these writers say, migrate to the urban communities from both the rural and the dense urban areas leaving the least able people behind. This leaves an increased proportion of inadequate people living in the undesirable extremes of density in addition to the unfavorable influences of these communities themselves. The conclusions of these Boston investigators must be accepted with reserve. The results point to the need for intensive study of communities of different population densities and characters and their influence on mental health.

MEDICINE AND THE WAR

ARMY

BAL IN OIL IN TREATMENT OF SEVERE MAPHARSEN REACTIONS

War Department Technical Bulletin of Medicine 104 dated October 12, announced the availability of a new drug, bal in oil, for use in the treatment of severe mapharsen reactions. Bal in oil is packaged in sterile ampules containing 500 mg of bal in 5 cc (10 per cent solution) of injectable material for intramuscular use only. It is stable when stored at ordinary temperatures. The bulletin discusses the selection of cases, the recommended dosage and reactions from bal in oil.

U S AND BRITISH ARMY MEDICAL OFFICERS HOLD MEETING IN FRANCE

U S and British Army medical officers recently held a three day meeting at a large U S Army general hospital in France, where they exchanged ideas on the treatment of battle casualties. This was the first conference of its kind in that theater.

Firestone Rubber and Latex Company at Fall River, Mass. Special tape produced by the Industrial Tape Company New Brunswick, N J is used in securing the canister and outlet valve to the plastic hood since natural rubber tape would form a tacky mass when attached to the vinylite plastic.

AAF REGIONAL SURGICAL CONFERENCES

During the month of September the Air Surgeon Major Gen David N W Grant, U S Army, through his Professional Division conducted six two day teaching regional surgical conferences for the medical officers of the Army Air Forces. The medical officers in the hospitals of the Army Service Forces, Army Ground Forces and the Navy adjacent to the conference hospitals were invited to attend as well as the civilian physicians in the immediate locality of the meetings. The conferences were held at Kearns Field Utah, Santa Ana Army Air Base, California, Aviation Cadet Center San Antonio Texas, Lincoln Army Air Base, Nebraska, Patterson Field Ohio and Drew Field Florida.

Medical officers who attended the three day meeting in France. Seated from left to right are Brigadier E Bulmer consulting physician to the British 21st Army Group, Lieut Col L M Rousselot commanding officer 108th U S Army General Hospital, Col F C Cutler chief consultant in surgery ETO U S Army, Brigadier A E Porritt consulting surgeon to the British 21st Army Group, Major Gen A G Biggam consulting physician to the British army, Major Gen Paul R Hawley chief surgeon ETO U S Army who called the meeting, Major Gen D C Monro consulting surgeon to the British army, Col J S K Boyd consulting pathologist to the British 21st Army Group, Col I C Kimbrough director of professional services office of the chief surgeon U S Army, Col W S Middleton chief consultant in medicine ETO U S Army. Standing in the second row back of Brigadier Bulmer is Brigadier Sir Stewart Duke Elder consulting ophthalmic surgeon to the British army. Next to him is Lieut Col G Heim senior consultant in cardiology ETO U S Army. At Colonel Heim's left is Brigadier George Riddoch consulting neurologist to the British army. Standing at the extreme right in the second row is Lieut Col B Brennan British medical liaison officer to the office of the chief surgeon U S Army.

HEAD WOUND GAS MASK DESIGNED BY CHEMICAL WARFARE SERVICE

The War Department recently announced that a gas mask to protect head wound patients from war gas has been developed by the Chemical Warfare Service and is now in production. The mask is the first such device which affords protection to patients with bandaged heads, faces or jaws and consists of a silklike vinylite plastic hood to which an air purifying canister and an outlet valve are attached. A flexible window across the eyes provides clear vision. Air is drawn into the mask by the ordinary breathing of the wearer. It is pulled over the head like a sack, the shimmering folds of the plastic cloth giving the wearer a luminous, ghostly appearance. The skirt of the hood fastens tightly around the neck, or a gastight seal can be obtained by taping the hem to the wearer's chest.

The head wound masks are being produced by the Bennington Plant of the National Carbon Company and by the

There was a total registered attendance of 884, or an average of 147 officers per conference representing 258 Army and Navy hospitals.

The programs at the six meetings contained 89 papers, an average of 15 per meeting, with discussions of such pertinent subjects as (a) the principles of wound healing, (b) the management of shock, (c) the management of chest injuries, (d) the management of head injuries, (e) the diagnosis and treatment of hernia, (f) chemotherapy in a surgical practice, (g) the use of regional anesthesia, (h) the treatment of pilonidal cysts and sinuses, (i) the treatment of more common anal and rectal conditions, and (j) the diagnosis and treatment of varicose veins. There were many excellent presentations from physicians of the Army Service Forces, the Army Ground Forces and the Navy, as well as from civilian practice. The scientific material presented in the papers and discussions is being abstracted for publication. The surgical staffs of four of the conference hos-

pitals and the Aero-Medical Laboratory of Wright Field, Ohio, presented most interesting and instructive scientific exhibits

This is the second of a series of regional surgical conferences conducted by the Air Surgeon. The first group of twelve conferences, on Fractures and Orthopedic Surgery, was held during the fall of 1943

COLONEL MENNINGER RECEIVES LASKER AWARD

The first annual Lasker Award in Mental Hygiene was recently presented to Col William C Menninger, chief consultant in neuropsychiatry, at the annual meeting of the National Committee for Mental Hygiene in New York City. The award this year was given for 'outstanding contribution to the mental health of the men and women of our armed forces'. The citation states that under Colonel Menninger's direction preventive psychiatry has been enhanced by a series of lectures on personal adjustment for all officers and enlisted men' and that through his efforts the emphasis on diagnosis and disposition has been shifted to active treatment, retraining and reconditioning for resumption of military duty or return to civilian life. The citation further states that 'Colonel Menninger has taken very much to heart the difficulties that confront the soldier discharged for neuropsychiatric disability. He has taken every opportunity and means to correct the popular misunderstanding of these diagnoses.'

SHIFT NINTH SERVICE COMMAND SURGEON

Brig Gen John M Willis surgeon of the Ninth Service Command since October 1943 will leave soon for an important overseas assignment, Major Gen William E Shedd, commanding general of the service command announced recently. Col Luther R Moore, former commanding officer of the Woodrow Wilson General Hospital, Saunton, Va, has succeeded General Willis.

NAVY

NAVY ESTABLISHES FILARIASIS REGISTRY

A filariasis registry was recently established by the Bureau of Medicine and Surgery at Marine Barracks, Klamath Falls, Ore, which is the reconditioning center for Marines returned to the United States from the Pacific because of malaria or filariasis.

The purpose of the registry is to make and keep a record in a central place of all Navy and Marine Corps personnel having a diagnosis of filariasis. Establishment of this centralized record keeping system will facilitate keeping filariasis patients under surveillance as long as they are on active duty. The information obtained will also make it easier to evaluate the extent of the problem presented by the disease and make possible an adequate follow-up system for effective handling of patients. All naval stations in the United States have been directed to examine health records so that if an entry of filariasis has been made for any individual the data can be forwarded promptly to Klamath Falls.

CHANGES IN NAVY MEDICAL CORPS COMMANDS

Capt William J C Agnew, Medical Corps, U S Navy, was recently appointed assistant chief of the Bureau of Medicine and Surgery. He will relieve Rear Admiral Luther Sheldon Jr, who has held the post since June 1940. Rear Admiral Sheldon will go to Norfolk, Va, as medical officer of the Fifth Naval District, succeeding Rear Admiral Joseph J A McMullin, Medical Corps U S Navy. The latter has been shifted to Boston as medical officer of the First Naval District, succeeding Rear Admiral Richard H Laning, Medical Corps, U S Navy. Rear Admiral Laning will assume the post of Inspector, Medical Department Activities Pacific Ocean Areas, recently vacated by Rear Admiral William Chambers, Medical Corps,

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Jesse G Heard

The Bronze Star was recently awarded to Lieut Col Jesse G Heard, formerly of Houston Texas. The citation accompanying the award read 'For meritorious achievement in connection with military operations against the enemy at Aitape, New Guinea, from July 2 to Aug 9, 1944. Lieutenant Colonel Heard, as chief of the surgical service, evacuation hospital, efficiently organized the surgical service, overcoming many difficulties by improvising surgical appliances, selection of surgical teams, formulating policies, surgical technic and procedures. His outstanding performance as operating surgeon, superior surgical judgment and leadership contributed directly to the success of the entire medical service connected with the military operation.' Dr Heard graduated from the University of Texas Medical Branch Galveston, in 1930 and entered the service in July 1942.

Major Champ Lyons

Major Champ Lyons, formerly of Mobile, Ala, was recently awarded the Legion of Merit. The citation read 'He initiated and guided the methods by which the new and potent agent penicillin has been utilized in the treatment of the seriously wounded. From the most forward mobile hospitals of Italy to the large general hospitals of the interior he has personally operated on and studied the treatment of the wounded, instructing his seniors and subordinates alike in a change of surgical procedures which is productive of better results. Lives and limbs of soldiers have been saved and the disability and deformity of wounds materially reduced. His professional judgment, combining a basic knowledge of the science of bacteriology with skill and experience in practical surgery, has cast new light on the age old problem of wound surgery. At no time has he spared himself mentally or physically, and the example he has set is an inspiration to all surgeons in the service.' Dr Lyons graduated from Harvard Medical School, Boston, in 1931 and entered the service Aug 11, 1943.

U S Navy, when he became medical officer in command of the National Naval Medical Center, Bethesda, Md.

Rear Admiral George C Thomas, Medical Corps U S Navy, (retired), has been appointed officer in charge of the newly established Professional Division in the Bureau of Medicine and Surgery. Since July 1943 Rear Admiral Thomas has been District Medical Officer of the Eleventh Naval District.

SPECIAL COURSE IN PHYSICAL TRAINING

Further reduction of sick days of personnel in Navy hospitals is expected as a result of the graduation of the sixth class of 4 physical training officers and 67 enlisted specialist personnel from the school established recently by the Bureau of Medicine and Surgery and the Bureau of Naval Personnel at the Naval Training Center, Sampson N Y. Eighty-seven officers and 388 enlisted men are already on duty in Navy hospitals carrying out a program of corrective exercises of graded intensity, designed to expedite the return to health of all types of casualties. With about 40 officers and 250 enlisted men in training at the Sampson Naval Training Center at any given time, classes of physical training personnel for assignment to Navy hospitals are graduated at weekly intervals. Personnel who majored in physical education in college in civilian life and who in many instances, had experience in corrective exercises were selected for this new duty.

To facilitate assignment to appropriate exercise groups, medical officers classify patients according to their ability to undertake physical activity. As progress is made toward recovery, reclassification is made to the next higher group. Physical education officers and enlisted specialists are responsible for actually supervising and conducting exercises for each of the various groups of patients. As part of the Navy medical department's broad rehabilitation program, they are subject to the command of medical officers in command in the various hos-

pitals At the present time, there are at least one physical training officer and several enlisted specialists on duty in all hospitals in full operation The number of officers and enlisted men in a particular hospital will depend on the needs of that hospital

NAVY MEDICAL OFFICERS ATTEND OPENING OF PENSACOLA SUR- VIVAL EXPOSITION

A Survival Exposition a permanent instruction exhibit providing graphic illustrations of survival afloat and ashore, was opened recently at the Naval Air Station, Pensacola, Fla The exhibit contains equipment developed under auspices of the Naval Medical Research Institute, National Research Council and other member agencies of the Air-Sea Rescue Agency It will be used as regular instruction material for ground training at the station The exhibits begin with the 'ditching' of a stricken plane by the pilot and crew and carry the visitor progressively through the ordeal of being adrift on rough seas

MISCELLANEOUS

HONORABLE DISCHARGE EMBLEM AUTHORIZED

A new Honorable Discharge Emblem has been adopted by the Army Navy, Marine Corps and Coast Guard under an agreement signed by Secretary of War Henry L Stimson and Secretary of the Navy James Forrestal Made of cloth and of the same design as the Honorable Service Lapel Button, it will be sewed above the right breast pocket of all outer uniform clothing at the time of discharge Honorably discharged personnel may wear their uniforms to their homes and thereafter at official ceremonies The basic design of the emblem will be embroidered in gold, with the background material varying to match the color of the uniform on which it is to be worn Supplies of the emblem are not yet available for distribution Regulations pertinent to the Honorable Discharge Emblem will be published in the near future

AID FOR BLIND VETERANS

Veterans Administration regulations issued recently, under authority of recently enacted legislation which permits seeing eye dogs to be furnished to blind veterans, stated that such veterans may be furnished the necessary travel expenses to and from their places of residence to the point where adjustment to the see eye or guide dog is available Meals and lodging during the period of adjustment will be provided in cases in which the veteran has to be away from his usual place of residence during the period of adjustment In addition, mechanical and electronic equipment considered as aiding in overcoming the handicap of blindness may also be supplied, the regulations state

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America (420 Lexington Avenue, New York 17) is preparing several cases of medical supplies and food to be shipped to Oran Algeria, and to southern France for the use of prisoners of war and their families Distribution abroad will be under the supervision of the "Comite de Secours aux Prisonniers de Guerre et a leurs Familles" The shipment will include baby foods canned apples and apricots cod liver oil, yeast tablets Eskay's tonic calcium phosphoric tablets Cartons, rectylsalicylic acid gauze bandages sulfonamide crystals, glycerin suppositories, milk of magnesia and Agarol

U S CADET NURSE CORPS

Dr Thomas Parran Surgeon General, U S Public Health Service Federal Security Agency recently announced that approximately 30,000 new student nurses have enrolled in the U S Cadet Nurse Corps this fall This is in addition to the 65,521 new student nurses admitted to the nation's nursing schools during the first year of the corps which ended June 30,

in rubber life rafts, planning salvation in polar or tropical regions and setting up temporary camp while awaiting rescue Life size manikins demonstrate how the aviator's survival paraphernalia together with the natural means of protection to be found in various regions, can best be used for survival In the 'Afloat' room the pilot and crew are shown adrift in rubber life rafts, employing the survival kits which are a part of the equipment of all naval aviators Around the walls of the room are shown the individual parts of the kit Birds, found at varying distances from shore are flown overhead, and in the ceiling pinpoint lights depict the constellations of the stars that can be used as navigational fixes

The exposition, which is in the charge of Capt Bertram Groesbeck Jr (MC), USN, was constructed under the supervision of Lieut Comdr Henry Nesburn (MC) USNR, whose experiences as a Navy flight surgeon in the Pacific enabled him to include in the exhibits situations confronting aviators in the Pacific This exhibit will be included in the ground school syllabus for flight students at Pensacola and marks a definite change in this element of ground training

1944 The Cadet Nurse Corps recruitment quota for the twelve month period ending June 30, 1945 is 60,000 new student nurses It is estimated that a total of 40,000 student nurses will have been enrolled between July 1, 1944 and Jan 1, 1945, so that the opportunity still awaits 20,000 qualified young women to join the corps when spring classes start, soon after the first of the year

RED CROSS WOMEN ON SHIPS

The first American Red Cross women assigned to Navy hospital ships will sail soon aboard the *Refuge*, marking the beginning of a new service requested by the Navy Red Cross workers formerly had been assigned only to Army hospital ships which give medical care and treatment while transporting patients overseas The two Red Cross hospital workers who will sail on the *Refuge* are Miss Leona McGowan of South Clinton, Iowa, in charge of Red Cross work on the ship, and Miss Katherine Bush of Santa Monica, Calif, who will assist her Both have been serving in Red Cross domestic hospital units

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service

(Continuation of list in THE JOURNAL November 18 p 777)

FLORIDA

St Vincent's Hospital Jacksonville Capacity 300 admissions 8 240
Sister Margaret Superintendent (resident—urology)

MINNESOTA

St Barnabas Hospital Minneapolis Capacity 208 admissions 6 20
Miss Nellie Gorgas Superintendent (intern Jan 1, 1945)

NEW JERSEY

St Mary's Hospital Passaic Capacity 237 admissions, 5 808
Sister Martha Eucharist RN Superintendent (interns)

NEW YORK

Our Lady of Victory Hospital Lackawanna Capacity 185 admissions,
4 143 Sister M Bathilde Superintendent (2 interns)

OHIO

Lima Memorial Hospital Lima Capacity 167 admissions 4 790
Mr Leslie O Fonkalsrud Administrator (1 intern 1 mixed
residency)

St Thomas Hospital Akron Capacity 175 admissions 5 392 Sister
M Eleanor RN Superintendent (2 interns Jan 1 1945)

OREGON

Emmanuel Hospital Portland Capacity 425 admissions 12 034
Mr A L Morland Superintendent (1 resident—orthopedics 1 resi-
dent—pathology 2 mixed residencies July 1 1945)

WEST VIRGINIA

Charleston General Hospital Charleston Capacity 380 admissions
10 200 Dr John E Cannaday Director (intern July 1 1945)

ORGANIZATION SECTION

Official Notes

THE PHILADELPHIA SESSION

Application Blanks Available for Space in the Scientific Exhibit

One of the features of the Philadelphia session will be the Scientific Exhibit to be held on the first floor of Convention Hall. Besides several special exhibits sponsored by the Committee on Scientific Exhibit of the Board of Trustees, there will be interesting displays presented by the medical departments of the Army, Navy and Air Corps, and many individual exhibits prepared by physicians, teachers and others.

Application blanks for space are now available and may be obtained from the Director Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

Washington Letter

(From a Special Correspondent)

Nov. 27, 1944

President Wants Research Continued

President Roosevelt has proposed that wartime scientific research be continued into the postwar era to improve national health and better national living standards and to stimulate employment. He expressed this view in a letter to Dr. Vannevar Bush, director of the Office of Scientific Research and Development, which has coordinated the application of scientific knowledge to war problems.

New frontiers of the mind are before us, the President said, 'If they are pioneered with the same vision, boldness and drive with which we have waged this war, we can create a fuller and more fruitful employment and a fuller and more fruitful life.'

Mr. Roosevelt asked Dr. Bush for recommendations on these four points: 1. What can be done, consistent with security, to give the world the scientific contributions made to the war effort? 2. With respect to combating disease, what can be done now to organize for the future the work done in medicine and related sciences? 3. What can the government do to aid public and private research? What can be done to develop scientific talent in American youth to assure progress comparable to that which has occurred during the war?

World Organization Covers Medical and Health Fields

Facilities for international medical and health programs are provided in the proposed United Nations organization planned at Dumbarton Oaks. An Economic and Social Council, to be a separate subsidiary to the main General Council, will be able to go into the field of international economic and social cooperation on a much broader basis than in the old League of Nations. The General Council would have the power to elect eighteen countries whose representatives would sit on this Economic and Social Council for three year terms. The number was limited to eighteen so as to create a workable body. On the Economic and Social Council each country would have one vote and its decisions would be made by simple majority. All the nations elected might be small nations though that is unlikely. The Economic and Social Council would recommend courses of action to the General Assembly. Decisions of the Economic and Social Council would not become laws regulating international commerce, immigration and emigration or sanitary labor and living conditions in any country. It could recommend courses of action to the General Assembly or provide information to the Security Council on international conditions affecting the peace of the world. Present independent social and economic agencies would take part on appropriate commissions. For instance, the United Nations Relief and Rehabilitation Administration and the International Labor organization would come

under the social and humanitarian commission. For the first time it is proposed to create a body to look at the whole world, see what goes on in living conditions, labor and commerce and recommend what might be done to keep nations from causing war.

Kelley Committee Resumes Hearings

Dr. Thomas Parran, Surgeon General of the United States Public Health Service, was one of the principal witnesses called when the Kelley Committee, a subcommittee of the House Labor Committee investigating ways and means of assisting disabled persons, resumed hearings. Dr. Parran was to testify Wednesday on proposed expansion of the Public Health Service, and its organization for disabled persons.

Paul V. McNutt, Administrator of the Federal Security Agency, and Katherine F. Lenroot, Chief of the Children's Bureau, Department of Labor, described the work of their organizations. First witnesses heard were J. C. Capt, Director of the Bureau of Census, and Michael J. Shortley, Director of the Office of Vocational Rehabilitation, Federal Security Agency. To be heard are A. F. Hinrichs, Commissioner of Labor Statistics, Department of Labor, Harry B. Mitchell, President of the Commissioners, Civil Service Commission, Oscar M. Powell, Executive Director, Social Security Board, and John W. Studebaker, Commissioner of U. S. Office of Education.

Physical disablement caused by the war and accidents in industry assisting the war effort constitute a problem concerning the entire nation," said Representative Augustine B. Kelley, Democrat, Pennsylvania, Committee Chairman. The subcommittee, created by H. Res. 230, was appointed by Representative Mary T. Norton, Democrat, New York, Labor Committee Chairman, and includes Representatives Jennings Randolph, Democrat, West Virginia, Thomas E. Scanlon, Democrat, Pennsylvania, Richard J. Welch, Republican, California, Stephen A. Day, Republican, Illinois, and Joseph Clark Baldwin, Republican, New York, with Samuel Barker, D. C. attorney, as counsel.

Medical Phone Calls Handled

Although Thanksgiving Day telephone service in Washington and in other strike bound areas at Detroit and Dayton, Ohio, was curtailed, emergency medical calls were given prompt attention by staffs replacing strikers. The situation, however, highlighted the seriousness from a medical standpoint of having national telephone service disrupted. Strikers called off the walkout just before the President was about to take over. Prompt attention to grievances was promised by the office of the President and the War Labor Board.

Dr. John Louis Parks Is Children's Bureau Consultant

Dr. John Louis Parks, professor of obstetrics and gynecology at George Washington University, has been appointed to serve as consultant in obstetrics to the Children's Bureau. He will advise the Children's Bureau on obstetric aspects of maternal and child health programs for which the bureau makes grants to state health agencies under the Social Security Act.

ILLINOIS

Joint Medical Meeting—A joint meeting of the Illinois Trudeau Society and the Lake County Medical Society was held at the Lake County Tuberculosis Sanatorium, Waukegan November 14. Dr David F. Loewen, Decatur, was chosen president-elect of the Illinois Trudeau Society and Dr William J. Bryan, Rockford, was inducted into the presidency. Dr Loren L. Collins, Ottawa, is secretary-treasurer. Among the speakers at the joint session were:

Dr W. Harrison Mehn, Waukegan, Penicillin Treatment of Tuberculous Empyema—Preliminary Observations
Dr Werner S. Prenzlow, Waukegan, Nontuberculous Conditions Encountered in Sanatorium Outpatient Clinic
Dr Henry C. Sweany, Chicago, X-Ray and/or Diagnostic Clinic
Dr Paul G. Dick, Chicago, Chest X-Rays in Industry

Chicago

Thomas Larsen Observes Fiftieth Anniversary at Chicago—In November Thomas A. Larsen, in charge of the stockroom of the laboratory supply department, University of Chicago, completed fifty years of service in the department and forty-two years of taking subscriptions for THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. Among the noted scientists who have subscribed to THE JOURNAL through Mr. Larsen are Drs. Edward V. L. Brown, Paul R. Cannon, George F. Dick, Ralph C. Hamill, Basil C. H. Harvey, Ernest E. Irons, Arno B. Luckhardt, Dallas B. Phenister, Wilber E. Post and the late H. Gideon Wells. Dean D. Lewis and Howard T. Ricketts. The service of three sons of Mr. Larsen to the university brings the total of family service to ninety years, twenty for one son, Ralph, and ten each for Glen and Leonard.

Annual Clinical Conference—The Chicago Medical Society will hold its second annual clinical conference at the Palmer House, Chicago, February 27-March 1. Among the speakers will be:

Dr Stanley Gibson, Heart Murmurs in Children: Interpretation of Their Significance
Dr George M. Curtis, Columbus, Ohio, Present Status of the Therapy of Hyperthyroidism
Dr Wingate M. Johnson, Winston-Salem, N. C., Management of Patient with Ulcer
Dr Clyde L. Randall, Buffalo, Bleeding At and After the Menopause
Dr C. Charles Burlingame, Hartford, Conn., Present and Future Effects of the War Neuroses
Dr I. E. E. Poole, Burbank, Calif., Coordination of the Activities of the Plant Physician and the Private Physician
Dr Robert Lee Sanders, Memphis, Tenn., Pre and Post Operative Treatment
Dr Herman L. Kretschmer, President, American Medical Association, Medical and Surgical Diseases of the Prostate
Col. William Paul Holbrook, M. C., Rheumatic Fever
Dr Eugene W. Secord, Detroit, Mistakes to be Avoided in the Application of Plaster Casts
Dr Irvine H. Page, Indianapolis, Hypertension
Dr Owen H. Wengenstein, Minneapolis, Bowel Obstruction
Dr Roger I. Lee, Boston, President-Elect, American Medical Association, Gynecitics
Dr Kendall Emerson, New York, Tuberculosis Wounds and Burns (speaker not announced)
Dr Otto Saphir, Visceral Changes in Polionovirus
Dr Edward L. Cornell, Prolonged Labor
Dr Theodore L. Squier, Milwaukee, Hay Fever and Asthma
Louis Schwartz, medical director, U. S. Public Health Service, Vocational Dermatoses
Dr Walter C. Popp, Rochester, Minn., X-Ray Therapy of Acute Infections
Surgical Lesions of the Lungs (speaker not announced)
Dr Philip M. Stum, New York, Advances in the Treatment of Infectious Diseases
Dr Edward Tolstoi, New York, Management of the Healthy and Sick Diabetic
Dr Marion A. Blankenhorn, Cincinnati, Pneumonia Arthritis (speaker not announced)
Dr Sidney Barber, Boston, Chronic Diarrheal Disorders in Young Children
Dr Peter C. Kronfeld, Chicago, Eye Conditions That Should Be Recognized by General Practitioners
Dr Earle B. Mahoney, Rochester, N. Y., Shock
Dr John W. Harris, Madison, Wis., Use and Abuse of Forceps
Dr John S. Lockwood, New Haven, Conn., Penicillin in Surgery
Lieut. Col. Hardy A. Kemp, M. C., Tropical Diseases
Dr John C. McKinley, Minneapolis, Problem of Social Psychopathy in Postwar Planning

Lectures will include a panel on endocrinology by Drs. Edward H. Ryncarson, Rochester, Minn., Ernest Perry McCullagh, Cleveland, Elmer L. Sebringhaus, Madison, Wis., Henry H. Turner, Oklahoma City, and George W. Thorn

Boston and a panel on nutrition by Drs. Morris Fishbein, Editor THE JOURNAL, Robert Elman, St. Louis, and Paul R. Cannon, Chicago. A panel discussion on hematology is also planned, the participants to be decided later.

INDIANA

Association Approves Health Insurance Plan—On November 12 the house of delegates of the Indiana State Medical Association in special session in Indianapolis adopted resolutions approving the inauguration of a prepayment health insurance plan. Details of the plan will be worked out by a specially appointed committee representative of the physicians both as to geographic distribution and as to kinds of practice. The final plans to be approved by the house of delegates again in special session. The Indianapolis News stated that the plan is of an indemnity type of insurance, under which persons participating would pay their medical and surgical bills with money received from the insurance company.

LOUISIANA

Personal—Dr. Marcelo Martinez Repetto, Merida, Mexico, is spending several months in New Orleans to study the causes and prevention of anemia, pellagra and intestinal diseases in local hospitals. This visit is part of a tour of the United States made at the invitation of the State Department.

University News—Dr. Roy R. Kracke, dean of the new University of Alabama School of Medicine, Birmingham, addressed the recent commencement exercises of the Louisiana State University School of Medicine, New Orleans, on 'The Physician's Obligation to Society'. Of the 79 graduates, 21 were in the Navy, 47 in the Army and 11 were civilians, 7 of whom were women.

MASSACHUSETTS

Personal—Dr. C. Walter Clarke, New York executive director of the American Social Hygiene Association, was recently appointed clinical professor of public health practice at Harvard University.

Harvard Society to Resume Meetings—The Harvard Medical Society held a meeting November 14 in the Peter Bent Brigham Hospital, Boston, the first since the beginning of the war. Meetings are planned for the second Tuesday of each month and a program will include the presentation of a clinical case, three papers of fifteen minutes each and a five minute discussion of each paper. According to the *New England Journal of Medicine*, this plan will make it possible for clinical studies to be offered as well as results of fundamental investigation.

MICHIGAN

Memorial to Physician—A part of the proposed new building for St. Luke's Hospital, Saginaw, will be dedicated in memory of the late Dr. Karl Kanzler as the result of a recent gift of \$50,000 in memory of the physician. The donation came from the Josephine and Ernest Kanzler Fund, of which Ernest C. Kanzler, Detroit, son of the physician, is president. Dr. Kanzler died in 1920.

Women Form New Medical Branch—On October 24 the Blackwell Society of Detroit and the Michigan branch of the American Medical Women's Association were merged; the new organization to be known as Blackwell Branch 20 of the American Medical Women's Association. Drs. Fanny H. Kenvon was named president-elect, Harriet I. E. McLane, president, Rose L. Herrold, vice president, Delma F. Thomas, treasurer, and Esther H. Dale, secretary, all of Detroit.

Changes in Health Officers—Dr. Gladys J. Kleinschmidt has been named health officer of Isabella County.—Dr. Alexander Witkow has resigned as health officer of Menominee County.—Dr. Homer G. Slade, on October 25, became director of district health unit number 4, including the counties of Alpena, Presque Isle, Montmorency and Cheboygan. He will have headquarters in Rogers City.—Dr. Georgia A. Mills has resigned as deputy health officer in Saginaw.

Chairman Named to Start Fund Raising Campaign—Wendell W. Anderson, president of the Medical Science Center of Wayne University, Detroit, has been named chairman of the first cycle of the medical center's fund raising campaign. Four buildings to be constructed in the first cycle program, the goal of which is about \$10,000,000, are the halls of the medical sciences to house the Wayne University College of Medicine, the college of pharmacy, the school of mortuary science, and allied programs; a university hospital for teaching and research; a classroom administration and dormitory build-

ing for the recently authorized college of nursing, and a powerhouse laundry and service building. The eventual goal of the Medical Science Center campaign is \$50,000,000 of which approximately \$20,000,000 will be for construction and equipment of buildings and \$30,000,000 for the endowment of program and research. The city plan commission has approved a fifty-three acre, fifteen block site for the Medical Science Center situated east of the Art Center. The corporation counsel has begun the condemnation of the first three blocks of this site.

MINNESOTA

Illegal Practitioner—On October 17 Elmer C Hultgren, Minneapolis was sentenced to a term of one year in the Minneapolis Workhouse following his plea of guilty to an information charging him with the crime of practicing healing without a basic science certificate. He was arrested September 16 following his attempt to perform an abortion on an unmarried woman at his apartment for which he received the sum of \$20. Hultgren admitted that he had no medical education of any kind, stating that three or four years ago he attempted to perform an abortion on another woman and that these 2 cases were the only ones in which he was ever involved.

Personal—Dr James M. Hayes formerly of Minneapolis, has been appointed assistant professor of surgery at the College of Medical Evangelists, Los Angeles.—Dr Audley V. Fankboner, who has had charge of the Range Hospital Buhl for the past eight years, has been named head of the medical department of the Walter Butler Shipbuilding Company with offices at the Riverside yard effective September 15.—On October 4 the Minnesota Public Health Association gave a dinner in honor of Dr Edward A. Meyerding St Paul in recognition of his twenty years of service with the association of which he is executive secretary. Dr Meyerding, who has been executive secretary since 1924, previously served as director of the division of hygiene of the St Paul department of education.

MISSOURI

Elmer Bartelsmeyer Dies—Mr Elmer H. Bartelsmeyer, executive secretary of the Missouri State Medical Association from 1933 to 1942, when he became consultant, died in St. Louis November 18, aged 54.

Alpha Omega Alpha Lecture—On November 10 Dr Joseph Earle Moore, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore gave the annual Alpha Omega Alpha Lecture at Washington University School of Medicine, St. Louis. His subject was 'Chemotherapy of Syphilis'.

Dr O'Reilly Honored—Dr James Archer O'Reilly, professor and head of the department of orthopedic surgery, St. Louis University School of Medicine, and president of the St. Louis and Missouri societies of crippled children was given a citation and medal for distinguished service to crippled children throughout the country during the twenty-second annual meeting of the National Society for Crippled Children at the Edgewater Beach Hotel, Chicago in October. Dr O'Reilly has been a member of the board of trustees of the national society since 1930 and has served as secretary and chairman of the Section on Orthopedic Surgery of the American Medical Association.

Postwar Plans for St. Louis University—A \$500,000 addition to the present building of the St. Louis University School of Medicine is planned in the \$2,600,000 postwar expansion program, according to Rev. Patrick J. Holloran, S.J., president of the university, in a statement to the press November 4. Plans have been completed and work will be started on the medical school immediately on release of permission by the war production board. Of brick and stone the new construction will be four stories in height and will contain a library and an amphitheater which will seat the entire student body. The proposed building program includes an addition to the nurses home, a new library, a new classroom building and a new dormitory. Two science buildings will be erected at a cost of \$250,000 each, one to house the physics and geophysics departments and the other the chemistry and biology classes.

NEW JERSEY

Physician Resigns as Dean of New Medical School—Dr Arcangelo Liva Hackensack, announces that he has resigned the deanship of the Essex College of Medicine and Surgery, Newark, which was scheduled to open November 4 (THE JOURNAL, September 9, p. 115, and November 4, p. 647).

NEW YORK

Child Guidance Center—The Westchester County Children's Association announces the opening of the Guidance Center, a service for children and young people of Westchester County. Two of the services offered by the center group demonstrations and the consulting service, have been available for some time, but the recent addition of a fee service includes adjustment of emotional, educational and behavior problems and vocational counseling and testing. The Westchester County Children's Association is located at 8 Church Street, White Plains.

Graduate Lectures—Dr Philip M. Stimson, associate professor of clinical pediatrics, Cornell University Medical College will give a graduate lecture on poliomyelitis before the Suffolk County Medical Society, Smithtown, December 6. Dr William F. Lipp, Buffalo gave a graduate discussion on the 'Treatment of Jaundice' before the Steuben County Medical Society, Bath, November 9. Dr Harry M. Rose, New York will address the Saranac Lake Medical Society, December 20, in the Saranac Laboratory on "The Diagnosis and Treatment of Meningitis." These lectures are sponsored cooperatively by the state medical society and the state department of health.

New York City

Personal—Philip S. Platt, Ph.D., who recently completed a current study of voluntary health agencies under the sponsorship of the National Health Council and for many years director of the Palama Settlement in Honolulu, T.H. has been appointed executive director of the National Association for the Blind.

County Medical Societies Consider Mayor's Health Plan—On November 17 the conference committee of the Health Insurance Plan of Greater New York met at the New York Academy of Medicine with presidents and other representatives of the county medical societies in the metropolitan area to explore the possibilities of their cooperation in developing the comprehensive medical service plan originally announced by Mayor Fiorello La Guardia early this year (THE JOURNAL, May 13, page 161). The conference stated that there had been an encouraging exchange of views and a second meeting was to be held December 1 at the academy of medicine.

NORTH CAROLINA

Seaboard Medical Association—The forty-ninth annual meeting of the Seaboard Medical Association of Virginia and North Carolina will be held at the Cherry Hotel, Wilson, December 5-7, under the presidency of Dr. Malory A. Pittman, Wilson. Among the speakers will be:

- Dr. Paul F. Whitaker, Kinston, Medical Care of the Future
- Dr. Rufus E. Raiford, Franklin, Va., Intravenous Anesthesia
- Dr. James Graham Ramsay, Washington, Torison of Omentum
- Dr. Antonio A. Burle, Norfolk, Va., Glaucoma with Especial Relation to Early Treatment
- Dr. Cleon W. Goodwin, Wilson, Enterogenous Cyst
- Dr. Charles Lydon Harrell, Norfolk, Remarks on the Early Approach to the Care of the Tuberculosis Patient
- Dr. Claiborne T. Smith, Rocky Mount, Chronic Noncalculous Cholecystitis
- Dr. Southgate Leigh, Jr., Norfolk, Treatment of Crushing Injuries of the Extremities
- Dr. Clayton W. Eley, Norfolk, Treatment of Sinusitis in Children by Ray
- Dr. Samuel A. Thompson, New York, Comparison and Value of Various Resuscitation Methods
- Dr. William C. Hunter, Wilson, Endemic Typhus Fever
- Dr. Randolph Bryan Grinnan, Jr., Norfolk, Coronary Occlusion
- Dr. Clarence P. Jones, Jr., Newport News, Va., Observations in Clinical Use of Prostigmin
- Dr. Russell von L. Buxton, Newport News, Treatment of Tetanus
- Dr. Albert G. Hahn, Hickory, Infantile Paralysis

A symposium on Rocky Mountain Spotted fever will be presented Wednesday afternoon by Drs. Coy C. Carpenter, Robert P. Morehead, Robert B. Lawson and George T. Harrell, Jr., all of Winston-Salem.

OKLAHOMA

Surgery Course Postponed—The ten weeks course of postgraduate medical study in surgical diagnosis which was to have opened in Tulsa, October 13, has been indefinitely postponed pending the employment of an instructor according to the Bulletin of the Tulsa County Medical Society. Dr. Archibald G. Fletcher, Philadelphia, who had been employed to present the course in the state during 1944 and 1945 has resigned (THE JOURNAL, Dec. 18, 1943, p. 1059). The course was to be offered under the auspices of the Oklahoma State Medical Association, with financial assistance from the Commonwealth Fund of New York and the state department of health.

PENNSYLVANIA

Personal—Dr Horace C Scott, Philadelphia, has been appointed deputy secretary of health of Pennsylvania in charge of Negro public health activities—Dr J Newton Hunsberger, Norristown, recently won the Challenge Trophy offered by the Professional Horsemen Association. The 78 year old physician rode to first place astride his 18 year old hunter, Highboy.

Philadelphia

Public Health Society Organized—The Public Health Society of the University of Pennsylvania was recently organized and held its inaugural dinner, November 8, at the Warwick Hotel, Philadelphia. Dr Angelo M Perri is president of the society, and Dr Mildred C J Pfeiffer, 331 S Smedley Street, Philadelphia 3, is secretary. Dr Perri was toastmaster at the dinner, and Lieut Col Arthur P Hitchens, M C, was guest of honor. Other speakers included Drs Stuart Mudd, professor of bacteriology, and Charles C Wolferth, professor of clinical medicine, at the school and Dr Rufus S Reeves, director of health of Philadelphia, Dr Hubley R Owen, director of medical services board of education of Philadelphia, and Dr Claude P Brown, assistant director state department of health laboratories. The society plans to hold bimonthly scientific sessions. Membership is not restricted to graduates of the University of Pennsylvania alone but is open to doctors of medicine, veterinary medicine and dentistry, social workers, sanitary engineers, public health nurses, political scientists and any one interested in the broad field of public health and preventive medicine.

TENNESSEE

Postgraduate Study—Dr Joseph R Bromwell Branch will conduct a postgraduate course in gynecology in western Tennessee the week of January 15, according to the state medical journal. He recently concluded the 1944 circuit of lectures and returned to the Novak Clinic, Baltimore. The state journal reports that the total number of registrants for these courses during the two years the state association has sponsored them is 1,391, including 991 civilian physicians and 400 medical officers of the Army, Navy and Marine Corps.

Faculty Changes—Dr Herbert S Wells Winston-Salem, N C, is acting professor of physiology at the University of Tennessee College of Medicine, Memphis. Dr Lathan A Crandall Jr, professor of physiology, is head of the department. Forrest R Davison, Ph D, Kalamazoo, Mich, has been named assistant professor of pharmacology to succeed Dr Lloyd D Seager, who has become head of the department of pharmacology at Woman's Medical College of Pennsylvania, Philadelphia. Other changes in the faculty at Tennessee include the resignation of Dr Howard Curl as assistant professor of anatomy to become assistant professor of radiology at the school.

WASHINGTON

New Executive Secretary—Mr Ralph W Neill for nine years correspondent for the Associated Press Bureau at Olympia, has been chosen executive secretary of the Washington State Medical Association, succeeding the late Arthur Anderson.

Director Named for State Division of Mental Hygiene

Dr George C. Stevens, who has been in charge of the development and operation of the mental hygiene program in Indiana for the past six years, has been appointed in charge of the newly established Washington division of mental hygiene. The creation of the new unit has been approved by the Washington State Medical Association, and a medical committee has been appointed to assist in developing a program which is a part of the general health plan of the state. The division will work closely with interested groups having responsibility for rehabilitating the returned veteran. A full time mental hygiene clinic is already in operation in room 320, Smith Tower, Seattle, and offers service to returned servicemen who have neuropsychiatric problems and to parents and others in child guidance who cannot afford other assistance. According to *Northwest Medicine*, as additional personnel become available it is planned to establish a second full time clinic in Spokane County, with a third clinic unit being made available on a traveling basis to all parts of the state as need arises. The psychiatric clinic service will necessarily be limited to those persons who would be unable to provide private care.

Proposed State Medical-Dental School—In a discussion of the proposed state medical dental school in connection with the University of Washington Seattle *Northwest Medicine* states that a recent survey disclosed that about 360 Washington residents are continually seeking medical education in other states and that about 116 residents must obtain their dental

degrees elsewhere. This circumstance would not be so alarming, it was stated, were it not for the fact that a high percentage of these persons, including many of those graduating in the higher brackets, fail to return to their home state to enter practice because of the opportunities offered elsewhere. It was pointed out that a medical-dental school in the state would be a magnet for prospective medical and dental students, not only of Washington but also of Alaska, British Columbia, Idaho and Montana. Replacements in the state have been "few and far between" in recent years. A recent survey disclosed that currently there is an average of only 1 physician to 1,765 persons in the state, compared with 1 physician to only 964 persons in prewar days. The journal points out that while legislation is required to establish the school the state medical and dental associations are planning to conduct a campaign for donations, contributions and endowments.

WISCONSIN

Ira Baldwin Named Dean of Graduate School at Wisconsin—Ira L. Baldwin, Ph D, professor and head of the department of bacteriology, University of Wisconsin, Madison has been appointed dean of the graduate school. Dr Baldwin, who during the past year has been doing war work in Washington under a leave of absence, will devote full time to his university work after December.

GENERAL

Pediatric Board Increases Fees—At the recent annual meeting of the American Board of Pediatrics, it was decided to increase the application fee to \$75, effective May 1, 1945.

Meeting of Anesthetists—The annual meeting of the American Society of Anesthetists will be held at the New York Academy of Medicine, December 14 under the presidency of Dr Emery A Rovenstine, New York. Among the speakers will be

Dr Ralph M Waters, Madison, Wis, subject not announced.
Dr Albert D Foster, New York, Peripheral Circulatory Responses During Anesthesia, Hemorrhage and Shock, the Use of the Digital Plethysmograph as a Clinical Guide.
Dr Solomon G Hershey, New York, Effects of Anesthesia on the Circulatory Response to Blood Loss.

Sessions on Industrial Health—The four national associations of professional workers in industrial health will meet at the Drake Hotel, Chicago, during the week of April 23. The National Conference of Governmental Industrial Hygienists will hold its meetings on April 23-24, the American Association of Industrial Hygienists will meet on April 25-26 and the American Association of Industrial Physicians and Surgeons' meetings are scheduled for April 25-27, the last day's sessions to be held jointly with the American Industrial Nurses Association, which will continue its sessions on April 27-28.

Special Society Elections—Dr Archibald D Campbell, Montreal, Que, was named president-elect of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons at its annual meeting recently and Dr Lewis F Smead, Toledo, Ohio, was inducted into the presidency. Dr James R. Bloss, 418 11th Street, Huntington 1, W Va, was reelected secretary. The next annual session will be held at Hot Springs, Va, September 6-8—Dr Frank R Bradley, medical superintendent of Barnes Hospital, St Louis, was named president-elect of the American College of Hospital Administrators. Dr Claude W Munger, medical director, St Luke's Hospital, New York, was installed as president.

Jackson Memorial Lecture—The first Jackson Memorial Lecture, named in honor of the late Dr Edward Jackson, Denver, was given by Dr William H Crisp, Denver, during the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago, October 11. The lecture is sponsored by the *American Journal of Ophthalmology* as a tribute to Dr Jackson, who was for many years editor of the journal. Dr Crisp's title was "Edward Jackson's Place in the History of Refraction." Dr Crisp had been associated with Dr Jackson on the editorial board of the *American Journal of Ophthalmology* and still holds a directorship in the publishing company and serves as an associate editor. Dr Jackson was elected president of the academy in 1906 and was the first to hold the office under the present name of the organization.

Child Welfare Information Service—The Child Welfare Information Service, Inc., was recently organized with headquarters in Washington, D C. According to the *State Charities Aid Association News* the service is designed as a national clearing house of information on federal legislation and the activities of federal agencies concerning welfare of infants, children and youths. The scope of the service includes security, recreation, child labor and related activities.

Eugene Meyer Washington, co publisher of the Washington Post is president. Other officers include Dorothy Canfield Fisher, Ph.D., Arlington, Vt., vice president, Mrs. Gertrude Folks Zimand, New York, secretary, and George J. Hecht, New York, treasurer. Bernard Locker, New York, assistant executive secretary of the State Charities Aid Association's welfare legislation bureau, has been named executive director of the new group, effective November 1.

Borden Award for Nutritional Research—The first annual Borden Award for nutritional research, given through the American Academy of Pediatrics, was presented at the wartime conference on child health in St. Louis November 10 to Major Harry H. Gordon, M.C. and Dr. Sam Z. Levine, assistant professor (on leave) and professor of pediatrics, Cornell University Medical College, New York, respectively. The award consists of a bronze medal with the inscription "Award for outstanding achievement in research in nutrition of infants and children and a prize of \$1,000." Major Gordon and Dr. Levine received the award for their work on "Metabolic Studies on Nutritional Requirements of Premature and Full Term Infants," the formal paper being presented by Major Gordon at the meeting of the academy November 11. Major Gordon has been stationed at Harmon General Hospital Longview, Texas since December 1942 and is currently chief of the malaria section.

Society News—The seventeenth annual convention of the Aero Medical Association of the United States will be held at the Palmer House, Chicago, September 24-26. Dr. David S. Brachman, 1016 Dime Building, Detroit 26, is the secretary. —The Society of American Bacteriologists will hold its 1945 session at the Book-Cadillac Hotel, Detroit, May 22-25. Leland W. Parr, Ph.D., George Washington University School of Medicine, Washington, D.C., is the secretary of the association. The association announces that Eli Lilly and Company is again offering a \$1,000 prize and bronze medal to a young man or woman working in a research or educational institution who is deemed to have done the most outstanding work in the field of bacteriology and immunology. To be eligible for the award a nominee shall not have passed his thirty-fifth birthday on April 30 of the year of the award. All nominations must have been received on or before February 15 for the 1945 award, the first announcement of the award to be made at the annual meeting of the Society of American Bacteriologists.

Medical Correctional Association—Dr. Robert V. Seliger, Baltimore, was chosen president of the Medical Correctional Association at its annual meeting in the Hotel Pennsylvania, New York, October 12. Other officers include Dr. Robert H. Felix, Washington, D.C., and Robert M. Lindner, Ph.D., Lewisburg, Pa., vice presidents and Mr. Edwin J. Lukas, New York, secretary-treasurer. The program of the meeting included discussion of "Treatment in the Postwar Prison—From the Point of View of the Psychiatrist," Dr. Marion R. King, of the psychologist, Benjamin Frank, supervisor of education, Bureau of Prisons, Department of Justice, of the physician, Dr. John W. Cronin, all of Washington. In addition the following spoke:

- Mr. Lukas: Alcohol and Crime
- Dr. Lawrence F. Woolley, Towson, Md.: Integration of Psychiatric Service with Court Procedures
- Dr. Seliger: What the Psychiatrist Wants from the Social Worker
- Dr. Lindner: Hypnoanalysis in the Treatment of Psychopathic Characters
- Dr. John D. Reichard, Lexington, Ky.: Tension, Its Study and Possible Role in Neurotic and Antisocial Behavior

The Medical Correctional Association is an affiliate of the American Prison Association, and the recent meeting was a part of the annual corrections' congress held in New York, October 12-15. Dr. Edwin J. Lukas is the secretary of the Medical Correctional Association which may be addressed at the Society for the Prevention of Crime, 122 East Twenty-Second Street, New York 10. Membership at \$1 a year is open to all interested persons.

Sectional Meeting of Federation for Clinical Research—The eastern section of the American Federation for Clinical Research will hold a meeting December 9 at the Massachusetts General Hospital, Boston. Included among the speakers will be:

- Dr. Sidney Scherlis, Staunton, Va.: Clinical and Stethographic Observation on Sounds Associated with Auricular Activity
- Dr. Gordon B. Myers and Benjamin G. Oren, Detroit: Use of the Augmented Unipolar Left Leg Lead in the Differentiation of the Normal from Abnormal Q Wave in Standard Lead III
- Dr. C. Cabell Bailey and Rachel S. Leech, B.S.: Boston Observations on Alloxan Diabetes with Special Reference to Blood Alloxan Determinations
- Dr. Edward C. Reifstein, Jr., Laurence W. Kinsell and Saul Hertz, Boston: Effect of Testosterone Compounds upon the Nitrogen Balance and Creatine Excretion in Patients with Thyrotoxicosis

- Dr. Elmer C. Bartels, Boston: Preoperative Use of Thiouracil in the Management of Severely Toxic Hyperthyroidism
- Drs. Richard S. Gubner and Murrill M. Szucs, New York: Comparative Study of Various Therapeutic Measures in 150 Cases of Rheumatic Fever
- Drs. Thiesen A. Ray and John S. LaDue, New Orleans: Intravenous Administration of Lanatoside C to Patients Taking Maintenance Doses of Folio Digitalis Up to the Date of Hospitalization with Recurrent Congestive Heart Failure
- Drs. Thomas M. Durant, Joan H. Long and Morton J. Oppenheimer, Philadelphia: Air Embolism: An Experiment Study of the Cardiac Manifestations
- Dr. Charles S. Davidson, Dr. John H. Freed and Francis H. L. Taylor, Ph.D., Boston: Methods of Estimating and Meeting Protein Requirements in Disease
- Drs. John T. Quimby and John H. Talbot, Boston: Blood Gas Values in Polycythemic States
- Dr. Joseph F. Ross, Boston: Hemoglobin Metabolism Studies with Radio-Active Iron in Normal Persons and Anemic Patients
- Dr. William B. Scoville, Frammingham, Mass.: Recent Developments in the Diagnosis and Treatment of the Cervical Ruptured Intervertebral Disc
- Drs. Henry J. Tagnon, William Goodpastor and S. N. Levinson, Boston: A Clinico-Pathological Correlation of the Kidney in Patients with Thermal Burns
- Dr. William G. Leaman, Jr., Philadelphia: Prolonged Use of Mercupurin in Congestive Cardiac Failure

FOREIGN

Campaign Against Leprosy—A grant approximating a million dollars has been allocated by the British government for a five year campaign against leprosy in Nigeria. The New York Times stated that this is the British taxpayers' latest contribution under the colonial development and welfare act passed in 1940. A high proportion of the people of the British empire live in the tropics, where leprosy is most prevalent. The Times stated in reporting an announcement from the British Information Service. In 1924 the British Empire Leprosy Relief Association was established to work with all existing antileprosy agencies. By 1944 they had twenty nine clinics in operation and 12,000 persons with leprosy were receiving treatment. In addition, fourteen model leper villages had been built.

Government Services

Robert Felix Placed in Charge of Mental Hygiene Division

Dr. Robert H. Felix has been appointed medical director in charge of the mental hygiene division in the bureau of medical services, U. S. Public Health Service. He succeeds Dr. Lawrence Kolb, who retired October 31. Dr. Felix, who was born in Kansas in 1904, graduated at the University of Colorado School of Medicine, Denver, in 1930. He was commissioned in the regular corps of the public health service in August 1933 and assigned to the medical center of the bureau of federal prisons at Springfield, Mo. In 1936 he left his position in Springfield as clinical director and went to the public health service hospital, Lexington, Ky., where he served as clinical director and later as executive officer for the medical and psychiatric rehabilitation of narcotic drug addicts. In 1942 he was sent to the U. S. Coast Guard Academy, at New London, Conn., where he developed and operated a mental hygiene service for coast guard cadets and applied psychologic and psychiatric tests in the selection of officer material.

Walter Treadway Retires from Public Health Service

Walter Lewis Treadway, medical director, U. S. Public Health Service, concluded more than thirty-two years in the public health service November 1 when he retired from active duty for disability incurred in service. Dr. Treadway had been stationed in Los Angeles since July 1941 as medical officer in charge of public health service activities. He graduated at the Barnes Medical College, St. Louis in 1907 and joined the public health service on July 28, 1913. He subsequently held many important assignments concerned with the mental hygiene activities of the public health service and from 1930 through 1938 was assistant surgeon general in charge of a newly created division of mental hygiene in the service. In 1938 he was detailed as medical officer in charge of the public health service hospital in Lexington, Ky. and in the following year was assigned to the University of California Medical School, San Francisco to collaborate with the California Department of Institutions and the university in the establishment of a department of psychiatry in the medical school and the creation of the Langley Porter Clinic. He remained in San Francisco until his assignment to Los Angeles in 1941.

Institutional Care of Young Children

Proposals to support a scientific inquiry into the effects on young children of being brought up in institutions are announced by the Nuffield Provincial Hospitals Trust. This inquiry is of particular importance at the present time, when so many children are being brought up in this way. Some sort of provision will have to be made in the future, as in the past, for the care of homeless, abandoned and handicapped children. But, although the impression exists that children brought up in institutions compare unfavorably in their adaptation to life with children brought up in normal homes, there is no scientific evidence on which a national policy can be based. The Nuffield Trust authorities are therefore making a substantial grant to the Provisional National Council for Mental Health to enable that body to undertake a carefully planned inquiry.

The widespread benefactions of the automobile magnate Lord Nuffield have been reported in previous letters to THE JOURNAL. Other recent grants made by the Nuffield Provincial Hospitals Trust are for the support of cancer research at Sheffield and to the department of child life and health in the University of Edinburgh for special study of problems of nutrition and dietetics in infancy and childhood.

Alterations Proposed for Royal Society of Medicine Building

The Royal Society of Medicine, the principal British medical society, is appealing to its fellows for \$250,000 to enlarge its premises. The number of fellows is now three times what it was in 1910, when the house at 1 Wimpole Street London W 1, was built, and the society's work is likely to expand. The proposed alterations include (1) a new top floor to contain a large room fully equipped for the clinical examinations, (2) an additional spacious library on the second floor approximately equal in accommodation to the present library on the first floor, (3) a third meeting room on the third floor, which can be used for discussions after clinical meetings, and (4) improved common room and committee room accommodations. The appeal is made with confidence that the Royal Society of Medicine has a brilliant future in accordance with its past traditions if the alterations can be made without being hampered by a building debt.

Return of University Students to London

The bombing of London led to the transfer of its educational establishments to safer places. Now with a great decline in the attacks the colleges are returning. The University of London is faced with the problem of finding accommodations for its students. About a third of College Hall the only London University hall of residence for women which closed at the beginning of the war, has been reopened for students. A third has been requisitioned by the government for the American Red Cross, and the other third was demolished in an early blitz. It can now take only 80 instead of the normal 170 residents. University College has taken over five bombed houses but their repair is held up by shortage of labor.

Radiolocation for the Blind

In the London Laboratory of Capt H G Round acoustics consultant of St Dunstan's Institute for the war blinded a radiolocation box has been invented by which a blind man will be able to recognize obstacles in his path. It consists of two pieces of electrical sound and light apparatus weighing

about 10 pounds and set on wooden boards. To it is connected a pair of ear phones. The first experiments in using the apparatus have shown it to be a success. The blind man can range-find with it, if the apparatus is set for 8 feet it makes a buzzing noise when any object is that distance away. It is hoped to develop a model weighing only 1 pound, which could be carried in the pocket. Experiments are also being made to produce a switchboard which can be operated by a man who has lost his hands.

RIO DE JANEIRO Sept. 25 1944

Dr George Pack in Rio de Janeiro

Dr George T Pack, from the Memorial Hospital of New York City, spent a few days in Rio de Janeiro as a special representative of the American College of Surgeons. Before several young doctors and medical students he operated on cancer patients at the Moncorvo Filho Hospital one of the newest municipal institutions, which is under the direction of Dr Helson Cavalcante. Dr Pack read papers on the treatment of cancer of the stomach and rectum and melanotic carcinoma at the National Academy of Medicine, at the Moncorvo Filho Hospital and at the Brazilian College of Surgeons, where he was received as a corresponding member. Dr Pack was invited to a luncheon at the Gavea Golf and Country Club where Dr A de Oliveira Lima secretary general of health for the Federal District (city of Rio de Janeiro), presented him, in the name of Mayor Henrique Dodsworth the welcome of the capital city of Brazil. Before leaving Dr Pack received from the Brazilian government the insigne of the highest honor of the order of the Cruzeiro do Sul (the Southern Cross).

Medical Films

The Bureau of Health Information of the Rio de Janeiro City Health Department, under the direction of Dr J F Fontenelle, in cooperation with the Division of Motion Pictures of the Office of the Coordinator of Inter-American Affairs a few weeks ago began the weekly presentation of technical films to the physicians of the city. Several films passed by the Board of Censors of the American College of Surgeons or prepared by the United States Public Health Service have already been shown, among which were those on modern local treatment of burns, the treatment of varicose veins, injuries to the face, surgical treatment of glaucoma the fight against malaria, the modern diagnosis of tuberculosis and the treatment of syphilis.

BACTERIOPHAGE ELECTRON MICROGRAPHS

To the Editor—The editorial "Bacteriophage Electron Micrographs" in *THE JOURNAL*, November 4, corroborates certain observations about the relative size of coli and staphylococci bacteriophages made in England and America approximately a dozen years ago.

In Britain, Elford and Andrewes (*The Sizes of Different Bacteriophages, Brit J Exper Path* 13 446 [Oct] 1932), employing graded collodion membranes (gradocol) and checking by diffusion through Jena sintered glass disks, concluded that coli phage particles had a diameter of about 30 millimicrons while *Staphylococcus* phage particles ranged between 50 and 75 millimicrons.

In this country, by far cruder methods, I observed that certain races of bacteriophage were able to pass through types of filters which others could not (Goldsmith, N. R. *Variations in the Filtrability of Different Races of Bacteriophage, J Bact* 33 495 [May] 1937).

Of four races of bacteriophage lytic for *Escherichia coli*, *Streptococcus hemolyticus*, *Streptococcus fecalis* and many staphylococci all of which passed Chamberland candles of various porosities only the first two were also able to pass through the Coors—a much finer filter. The variations in filtrability were not altered by the age of the filtrates by storage temperatures, by contacts with the homologous cultures or by mixtures with definitely filtrable races of phage. Although not proved by the filtration experiments it is suggested that the observed variations in filtrability are due to differences in the size of bacteriophage races.

Luria, Delbruck and Anderson, referred to in your editorial (*Proc Nat Acad Sc* 28 127, 1942; *J Bact* 46 57, 1943), note that one staphylococcus phage was found to be about twice the size of a coli phage in all dimensions, or eight times its volume.

At the time of my observation it was felt that variations in size were responsible for the differences in filtrability, although it was recognized of course that there are many factors determining filtrability. Luria's findings indicate that perhaps my original conception may be near the truth.

NORMAN R. GOLDSMITH, M.D., New York

THE MALE CLIMACTERIC—A MISNOMER

To the Editor—Among the numerous male patients complaining of various functional nervous disorders, including sexual impotence Heller and Myers (*THE JOURNAL*, October 21, p 472) found 23 who had pronounced elevation in gonadotropic hormone excretion, comparable quantitatively to that occurring in castrates. Testicular biopsy done on 8 of these patients revealed reduction in size and in activity of the seminiferous tubules and reduction in size and number of Leydig cells. Three times hyalinization of the seminiferous tubules was found. The age of those patients varied from 25 years to the seventh decade. They made a striking improvement after parenteral administration of testosterone propionate. They are considered to be "true examples of the male climacteric." Heller and Myers emphasize that their findings are by no means a physiologic accompaniment of the aging process in the male. "It is a relatively rare syndrome, probably affecting only a small proportion of men who live into old age."

Further investigation and corroboration seem to be necessary with regard to the following statements of Heller and Myers:

1 The large number of clinical symptoms listed in their table 2 is encountered in both groups of patients, those with

and those without evidence of testicular failure. Testosterone propionate injected or implanted is effective only in the first and not in the latter group of patients. It is surprising that in the latter group diagnosed as psychoneurosis not one patient should have responded to this treatment. Any kind of treatment should have had at least a psychologic effect in one or another of those psychoneurotic persons.

2 According to Heller and Myers there is a sharp line of separation between the "male climacterics" and the psychoneurotic, there is no room for transitional or mixed cases. This is surprising since in female climacterics such a mixture and amalgamation of hypo ovarian and psychoneurotic symptoms is the rule rather than the exception.

3 Why has oral or sublingual administration of methyl testosterone been quite ineffective?

4 Hot flushes are characteristic of the female climacteric. I never encountered them as a spontaneous complaint in men. Are they not the result of suggestive questions asked by the physician?

5 Treatment with injections of testosterone resulted not only in alleviation of the symptoms but also in a pronounced drop of the elevated level of the excreted gonadotropic hormone. If Heller and Myers believe that the elevation of gonadotropins in testicular insufficiency is due to failure of utilization of this hormone by the testes, how do they explain the effect of parenteral testosterone administration on the amount of gonadotropin in the urine?

On the grounds that the syndrome reported by Heller and Myers occurs as a rare and pathologic accompaniment of the aging process and that among 23 patients it was observed three times in men under the age of 30, I should prefer calling the syndrome "testicular insufficiency" rather than "male climacteric." I see no reason to change my standpoint expressed in the monograph "Constitution and Disease Applied Constitutional Pathology" (New York, Grune & Stratton, 1942, p 83). "If the term climacteric is used, as it should be, to designate the cessation of the gonadal activity at a definite period of life, with all the consequences brought about by such an elimination of the gonads from the endocrine system, then there is little justification for using the term male climacteric. The functional activity of the testicles slackens with advance in years. There is, however, neither generally nor individually a definite age at which the testicles stop functioning as do the ovaries. Flushes, vasomotor crises and sudden attacks of perspiration characterize the menopause, these do not occur, however, in males. The rise in concentration of gonadotropic pituitary hormone in the urine of women at the menopause is not to be observed in men with advance in years. There is not sufficient foundation for calling the whole gamut of neurasthenic complaints occurring in men between 45 and 60 climacteric, just because a mental depression may be associated with sexual impotence."

MEDICOLEGAL ABSTRACTS

Chiropractic Practice Acts Texas Act Unconstitutional and Void—A separate chiropractic practice act was enacted in Texas in 1943 (Acts 1943 ch 359) creating an independent board of chiropractic examiners to examine and license applicants qualified as set out in the act for licenses to practice chiropractic as defined in the act and making it a misdemeanor for any unlicensed person to practice chiropractic or for any person to advertise as a chiropractor without following his name with the term 'chiropractor'. Halsted was charged in the county court of Johnson County, Texas with practicing chiropractic without a license and with advertising as a chiropractor without following his name with the term 'chiropractor'. He was arrested and taken into custody and subsequently he instituted in the district court, Johnson County, habeas corpus proceedings for discharge from that arrest. He contended that the chiropractic practice act was unconstitutional and void and that the offenses charged against him were not based on any valid law. He was denied relief, was remanded to custody and appealed to the court of criminal appeals of Texas.

A provision in the Texas constitution, said the appellate court, permits the legislature to pass laws prescribing the qualifications of practitioners of medicine in Texas but expressly provides that no preference shall ever be given by law to any schools of medicine (Texas Constitution art 16, sec 31). By authority of this provision as well as by the general police power to protect the public health, the legislature has in the medical practice act expressly defined the practice of medicine and has prescribed rules and regulations governing its practice. That act provides that any person shall be regarded as practicing medicine who for money or other compensation treats or offers to treat any disease or disorder mental or physical or any physical deformity or injury, by any system or method (Vernon's Penal Code, art 741). The medical practice act, as well as the definition of practicing medicine just adverted to has been sustained as valid not only by this court but by the Supreme Court of the United States. In construing the medical practice act and in determining what constitutes the practice of medicine thereunder, this court has consistently held that one who publicly professes to treat diseases or disorders as a profession or avocation is practicing medicine, regardless of the system or method employed, the name by which the system is known, or whether or not drugs or surgery are used. The practice of medicine as contemplated by the medical practice act is not restricted to the treatment of diseases and disorders of the human body by the use of drugs or surgery and embraces the practice of chiropractic and osteopathy similarly and did embrace the practice of optometry prior to the passage of the optometry practice act. It is apparent that by the passage of the chiropractic practice act the legislature intended to take the practice of chiropractic out of the field of the practice of medicine as defined in the medical practice act, to set up chiropractic as an independent science separate and distinct from the practice of medicine and by special treatment and classification, to authorize practitioners of chiropractic to treat diseases of the human body. So then, the question before us is whether or not the act expresses the legislative intent in a valid definite understandable law. If so, did the legislature have the authority to enact such a law?

With respect to the question as to whether or not the act before us and the court is a valid definite understandable law, the definition the legislature gave to the term chiropractic in the act is of paramount importance. The term is defined in sections 3 and 3a of the act as follows:

Sec 3. Chiropractic is defined to be the Science [sic] of analyzing and adjusting the articulations of the human spinal column and its connecting tissues without the use of drugs or surgery. Chiropractic shall in no sense be construed or defined as treatment or attempted treatment of patients by use of surgery or medicine. It is hereby declared

the purpose of the Legislature to make as definite the distinction between Chiropractic and other sciences as the distinction between Dentistry and Medicine.

Sec 3a. No chiropractor shall treat any patient for any ailment or illness except by chiropractic as that term is herein defined. Provided that it shall be a violation of this Act for any person licensed hereunder to treat any person for infectious or contagious diseases or to engage in the practice of medicine.

Section 3 it will be noted is divided into two parts, one positive the other negative that is to say, one sets forth what chiropractic is while the other sets forth what it is not. These taken together constitute the definition of chiropractic. By the positive, chiropractic is the 'science of analyzing and adjusting the articulations of the human spinal column and its connecting tissues, without the use of drugs or surgery'. Under the negative Chiropractic shall in no sense be construed or defined as treatment or attempted treatment of patients by use of surgery or medicine. It is not the practice of medicine but is separate and distinct therefrom. The terms surgery and medicine not being specially defined are used in the sense in which they are commonly understood. So then under section 3 it may reasonably be said that chiropractic is the science of analyzing and adjusting the articulations of the human spinal column and its connecting tissues without the use of drugs or surgery, and that it is not the practice of medicine as defined in the medical practice act but is separate and distinct therefrom. Section 3a of the act states the rights, powers and privileges conferred on chiropractors that of necessity have a bearing on and become a part of, the definition of chiropractic for whatever a chiropractor may lawfully do as a practitioner becomes a part of the definition of the practice. The first part of section 3a prohibits a chiropractor from treating a patient except by chiropractic as defined. By the application of familiar rules of statutory construction that means that a chiropractor may treat a patient for an illness or disease, except infectious and contagious diseases, by chiropractic but in the same section it is made a violation of the act for a chiropractor "to engage in the practice of medicine which as we have shown, means, of necessity, that a chiropractor by chiropractic was prohibited from treating or offering to treat diseases or disorders of the human body for compensation. Section 3a therefore by its terms authorizes the chiropractor to treat patients for all ailments and diseases except those that are infectious and contagious, and, at the same time makes it unlawful for him to do so. As thus construed sections 3 and 3a are in irreconcilable conflict, for by the terms thereof, a chiropractor is both permitted to treat and is prohibited from treating patients for illnesses and diseases. He is both within and without the provisions of the medical practice act defining the practice of medicine. Such being true it is impossible from the wording of the act, to determine what is chiropractic and the practice thereof and whether the same is or is not the practice of medicine under the medical practice act, as judicially determined.

The chiropractor recognized this conflict between sections 3 and 3a but insisted that what the legislature intended in prohibiting a chiropractor from practicing medicine was that he could not practice medicine by means or methods other than those comprehended in the practice of chiropractic and that so long as he treated patients by chiropractic he was not practicing medicine. But answered the court, if the chiropractor's views are accepted then the validity of the chiropractic practice act depends on the power of the legislature to say that one who treats a patient for noncontagious or noninfectious diseases or disorders by analyzing and adjusting the articulations of the human spinal column and its connecting tissues, and without the use of drugs or surgery, is not practicing medicine within the meaning of the medical practice act. This resolves itself to the question as to whether or not the legislature has the power and authority to pass such a law, and thereby to create and to set aside as an independent class treatment of diseases and disorders of the human body by chiropractic. There is no question but that the legislature is authorized to regulate and control the treatment of diseases and disorders of the human body. The legislature also may make reasonable classifications of practitioners in that field and such classifications are not inhibited by the provisions of the federal constitution prohibiting class legislation. This was recognized as not prohibiting

the legislature from passing the optometry practice act and appears also as the doctrine on which the validity of the acts of other states controlling and regulating the practice of chiropractic has been upheld. But in this state the authority of the legislature to enact legislation touching the practice of medicine or the healing art has been expressly limited by that provision of our state constitution providing that no preference shall ever be given by law to any school of medicine. No similar constitutional provision is in effect in any other state and therefore the fact that other states have authorized the practice of chiropractic as an independent field of endeavor, as being outside the field of the practice of medicine is of no consequence or relevancy here. The chiropractic practice act of Texas must be construed in the light of the Texas constitution.

The fact continued the court that we have previously upheld the constitutionality of the separate dental and optometry practice acts enacted in this state has no bearing whatsoever on the right of the legislature to enact a separate chiropractic practice act in this state. Admittedly there is no question as to the constitutionality of the optometry practice act or of the dental practice act. In both cases the legislature restricted the practitioners of optometry and of dentistry to a particular part of the body. In the case of optometry the optometrist is expressly precluded from treating the eye for disease or disorder and from treating for diseases and disorders of the human body. In the case of dentistry the dentist is restricted to a certain part of the human body and is not authorized to treat the body generally for a disease or a disorder. Chiropractic on the other hand relates to the whole of the body and authorizes the treatment thereof for diseases or disorders.

The final question to be determined by the court was whether or not the chiropractic practice act was in violation of that clause of the Texas constitution which provides that no preference shall ever be given by law to any schools of medicine. This provision said the court has been the basis on which has rested the legislative control over and definition of the practice of medicine. It furnishes the direct reason why the courts have steadfastly held that if one treats or offers to treat as a business profession or avocation diseases of the human body by any method system or means he must first qualify himself to do so by taking the same examination that is required of all others doing the same thing regardless of the system employed. The term schools of medicine used in the constitutional provision referred to has reference to the system means or method employed or the schools of thought accepted by the practitioner. Under the medical practice act one desiring to practice medicine must possess certain qualifications as to character and educational attainments and must pass a satisfactory examination on certain basic subjects. Under the chiropractic practice act one desiring to practice chiropractic must also possess certain qualifications of character and educational attainments and must pass a satisfactory examination on certain basic and special subjects. The educational qualifications imposed by the medical practice act and the chiropractic practice act materially differ those qualifications imposed by the medical practice act being decidedly more onerous. Assuming then that under the chiropractic practice act the legislature has set up recognized and defined chiropractic as a separate system for the treatment of diseases and that practitioners thereof are authorized to treat, by chiropractic, patients for diseases and disorders it is evident that the legislature has preferred chiropractic and chiropractors over all others engaged in treating the human body for diseases and disorders because the chiropractor is not required to have the same educational qualifications nor is he required to pass examinations in the same subjects that are required of others similarly situated. The preference accorded the chiropractic system does not stop there for we know that prior to the enactment of the chiropractic practice act one who had qualified under the medical practice act was at perfect liberty to practice by the chiropractic system, or by any other system that to him seemed proper. The law did not control or attempt to control the licensed practitioner under the medical practice act in the system, means or method he employed. All that the law required was that if one treated diseases as a calling he must first qualify himself to do so by passing satisfactorily the examination required of all others similarly situated and coming within the same class. This is no longer true under the chiropractic

practice act because even though one be licensed to practice medicine under the medical practice act he cannot employ a chiropractic system of treating diseases without taking and passing the examination required under this act. Thus the legislature has carved out of the field of the healing art a single system for treating diseases and has given it special treatment, limiting its use to those who qualify under the chiropractic practice act. It seems clear that this legislation violates the nonpreference clause of the Texas constitution.

When this act is construed as an overall picture, said the court the practice of chiropractic is either definite or indefinite, certain or uncertain. If it is indefinite or uncertain, it falls by reason thereof. If it is definite and certain it violates the nonpreference clause of the state constitution. It follows, therefore that the chiropractic practice act is unconstitutional and void, that there exists no valid law denouncing as a crime the practice of chiropractic by one not licensed specifically so to do and that Halsted is entitled to be discharged.—*Ex parte Halsted* 182 S W (2d) 479 (Texas 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Pericarditis Associated with Primary Atypical Pneumonia D. Finkelstein and M. I. Khuner —p. 385

Auricular Infarction—According to Young and Koenig auricular infarction as a distinct entity is rarely reported. They report 3 cases of distinct auricular infarction without ventricular involvement. A fourth case in which the electrocardiograms showed changes apparently typical of auricular damage proved to be one of ruptured false aneurysm with hemorrhagic infiltration of the auricles. In 3 of the 4 cases there were deviations of the P-T segments conforming to that described as typical of auricular damage. In one there was also an apparent disturbance of the auriculoventricular conduction pathway, this was most likely due to the ulceration through the interventricular wall. All of the infarcts were located in the right auricle.

Clinical Experience with Dicumarol—Geffer and his associates used dicumarol for 30 patients with thromboembolic disease. There were 14 cases of peripheral arterial occlusion, 1 case of coronary artery occlusion, 4 cases of cerebral artery occlusion, 2 cases of subacute bacterial endocarditis, 4 cases of pulmonary artery occlusion, 1 case of retinal vein thrombosis, 3 cases of thrombophlebitis and 1 case of what was probably hepatic vein thrombosis. No changes were observed in the leukocyte count, hemoglobin, blood sugar, blood urea nitrogen, van den Bergh, icterus index, bromsulphalein retention, urine specific gravity, albumin, sugar and iodized elements. On the dosage schedule of 300 mg orally for two days and 50 mg daily thereafter the plasma prothrombin fell rapidly from 80 per cent to 25 per cent of normal in three days, was 20 per cent or less from the fourth to ninth days and then rose slowly to a level of 50 per cent in four weeks, where it was subsequently maintained. Coincidentally the clotting time rose from four minutes to a level of six minutes in three days, was six minutes or more from three to ten days and then fell slowly to a level slightly greater than normal in four weeks. The bleeding time was unaltered. Of the 30 patients 7 died and 23 recovered. Improvement in the peripheral vascular circulation was demonstrated in 6 of 8 cases studied. Hemorrhage, the sole mani-

festation of toxicity was observed in 5 cases in all of which recovery occurred. The only reliable method of ascertaining the proper dose of dicumarol is by frequent plasma prothrombin determinations.

March Fracture—Krause and Thompson report a study on 200 soldiers with 220 march fractures of the metatarsals. The immediate cause of the fracture is the rhythmically repeated subthreshold traumas incident to marching which acting by summation, reach a point beyond the ability of the bone to bear stress. Fatigue of the calf muscles causes these subthreshold injuries to be accentuated. Observations on the 200 men with march fractures and on 400 controls revealed that these fractures usually occur within the first six months of training especially among infantrymen. The second and third metatarsals are most frequently involved. One half of the fractures are seen and can be diagnosed before callus formation occurs. The fractures vary in extent from a narrow 'hair line' to actual comminution. A small proportion (7 per cent) cannot be diagnosed on the first examination but will be apparent on reexamination after a few days. Careful study of technically perfect roentgenograms is a requisite. The nature of the soldier's previous occupation and his body build have no relation to the cause of march fracture. The presence of a short first metatarsal is not a predisposing cause. A slender foot does not appear to be a significant predisposing cause. The authors think that these fractures will continue to occur in the course of training soldiers. The most important fact is that early recognition and proper conservative treatment restore these men to duty with a minimum of lost time.

Peptic Ulcer of Greater Curvature of Stomach—Blum stresses the rarity of benign ulcers of the greater curvature of the stomach, pointing out that only 15 proved cases have been found in the literature. The real incidence of these ulcers is unknown, mainly because of lack of histologic proof and inadequate follow up of the cases reported. The author reports the history of a patient with a large ulcer on the greater curvature which was demonstrated roentgenographically and proved by surgical resection and histopathologic examination. The patient is alive and well, without symptoms of peptic ulcer, six months postoperatively. According to the literature and the best medical opinion, a niche located on the greater curvature of the stomach should be considered malignant until proved otherwise.

Roentgenologic Observations in Mesenteric Thrombosis—Rendich and Harrington describe roentgenologic observations in 3 cases of superior mesenteric thrombosis. There was one common and striking finding in the plain roentgenogram of the abdomen in these cases which the authors believe has some diagnostic merit, namely, distention of the small bowel and the right half of the colon simulating a mechanical obstruction. The gas collection ended abruptly at the left end of the transverse colon. The distended bowel corresponded to the

distribution of the superior mesenteric vessels. In 1 case a barium enema was given and no mechanical lesion was found although expected by the sharply demarcated distention down to the splenic flexure as noted in the flat roentgenogram of the abdomen. This observation suggests the possible value of a sign complex in the diagnosis of superior mesenteric occlusion: the free passage of the barium through a section of intestine so distended as otherwise to suggest a mechanical obstruction. One of the 3 patients whose histories are reported died. The other 2 patients made a complete recovery after bowel resection. The literature indicates that distention is a frequent symptom in mesenteric thrombosis. The authors deplore that roentgen examination of the abdomen is too often neglected in the presence of acute abdominal symptoms. They think that the roentgenologic observations in their 3 cases suggest that the possible diagnosis of thrombosis of the superior mesenteric vessels should be among those considered when the plain roentgenogram of the abdomen discloses bowel dilated down to the region of the splenic flexure, simulating a mechanical obstruction. If a subsequent barium enema reveals no obstruction, it is believed that the diagnosis may be ventured with some probability.

Sulfathiazole Gum in Secondary Post-Tonsillectomy Hemorrhage—According to McGovern, secondary hemorrhage takes place usually from three to fourteen days after operation, often at the time the slough is separating from the tonsillar fossa. The methods of controlling secondary hemorrhage include blood transfusion, injection of the fossa with a solution of procaine hydrochloride and epinephrine hydrochloride and local application of astringents and coagulants. Most often the gentle removal of the clot, sedation with a morphine salt and pressure applied to the fossa with cotton sponges are sufficient to control the bleeding. Cauterizing the bleeding point with a saturated solution of silver nitrate is often successful, provided the silver nitrate can be accurately applied to the dried area. Cunningham found the local application of powdered sulfapyridine to be effective in the control of vascular oozing in delayed tonsillar hemorrhage. Preliminary study of the effects of routine postoperative use of sulfathiazole gum indicated a reduction in the incidence of secondary hemorrhage. The gum used contained $3\frac{3}{4}$ grains (25 mg.) of sulfathiazole. When the gum was chewed for one-half to one hour the average salivary concentration of sulfathiazole was 70 mg. per hundred cubic centimeters. The blood sulfathiazole of children chewing one tablet for one-half hour for twelve daily doses showed a maximal concentration of 0.5 mg. per hundred cubic centimeters. Adults chewing two tablets for the same period showed a peak concentration of 0.8 mg. per hundred cubic centimeters. The gum is pleasant, practical, simple to administer and well tolerated by the patient; no untoward effects have been noted. The dose is one to two tablets chewed for one-half to one hour, four to six times a day, depending on the age and the weight of the patient. A preliminary study of the routine use of sulfathiazole gum after tonsillectomy indicated a reduction in the incidence of secondary hemorrhage.

Carcinoma in Young Persons—Morehead presents the histories of 2 patients in whom carcinoma of the cervix occurred at or below the age of 20. Adenocarcinoma constitutes only about 5 per cent of the epithelial cancers which arise in the cervix, yet of the 15 reported cervical cancers proved to be carcinoma in persons 20 years of age or under more than two thirds were adenocarcinomas. Squamous cell carcinoma is rapidly fatal in the young, while adenocarcinoma offers a much better prognosis. Three cases of carcinoma of the body of the uterus arising under the age of 30 have been added to those already reported. The course of fundal neoplasms occurring in young persons appears to be influenced mostly by the morphologic type. It has been impossible to determine the influence of age on the morphologic type of these tumors. Primary carcinoma of the liver characteristically occurs between the ages of 40 and 60, but the disease has been seen in newborn infants, and Steiner has collected 75 cases in which it arose during childhood. In 41 of these cases it occurred before the age of 2 years. The occurrence of carcinoma of the liver in infants and young children suggests that at least in some cases congenital factors may play a part in the etiology. The disease is rapidly fatal, and age does not influence its course or morphologic character. To those tumors diagnosed as primary carcinoma of the liver which have been reported as occurring in young persons the author has added 2 more, 1 in a boy of 13 and the other in a youth of 18.

Coccidioidomycosis—Lee says that all new personnel coming to the air fields are skin tested, and the negative reactors are retested six months later. All suspicious clinical cases in the dispensaries and hospitals are skin tested, and in addition specimens of blood are sent to the Army Epidemiological Board for confirmatory evidence when indicated. Over a quarter of a million skin tests have been given, a thousand or more clinical cases recognized and nine complete necropsies done. The author differentiates three forms of coccidioidomycosis: primary, intermediate and advanced. The primary form is usually subclinical. The only evidence of its having occurred is the finding of a positive skin test in an individual who was previously negative. This will occur in about 10 per cent of personnel, but some stations have reported as high as 80 per cent of the post population turning positive. Frequently, what would ordinarily pass as a cold, mild influenza or "desert rheumatism" is properly diagnosed as coccidioid infection. When erythema nodosum occurs the diagnosis is suspected much more frequently. The intermediate (or pulmonary) stage is the one which is most frequently recognized clinically. This is an acute, subacute or chronic pulmonary inflammation. It resembles tuberculosis. Cavities occur frequently, but they show a great tendency toward spontaneous closure. The advanced or disseminated form is about 100 times as likely to occur in the Negro as in the white soldier. Dissemination, if it occurs, is likely to occur early. If there are going to be late disseminations the problem

will be very difficult. In the disseminated cases almost every organ of the body has been involved. The body may be literally riddled with cold abscesses. There have been a few cases of dissemination in which apparent recovery occurred. That dissemination may be impending can often be anticipated from a rising titer in the complement fixation test. There is no effective treatment.

Cheese Borne Epidemics of Typhoid—Meyer states that during the months of April and May the California State Health authorities were greatly baffled by an increased incidence of typhoid in four counties. All of the 77 cases were due to type C *Eberthella typhosa*. Epidemiologic inquiries revealed that all patients had consumed unpasteurized Cheddar cheese of the unripened variety. Persons who had eaten the cheese in cooked form were not attacked. The literature on epidemics of typhoid caused by cheese shows that the infective agent invariably reached the cheese through the use of raw milk accidentally contaminated by a carrier or an ambulatory patient. Adequate pasteurization of the milk, or pasteurization at any stage in the cheese making process should render fresh, unripened cheese safe. The consumer and the industry continue to argue as to whether or not the flavor is destroyed or the quality is injuriously affected by heating the milk. Other means have been suggested. Since ripening requires weeks or several months, it has been stated that cured cheeses of the Cheddar type are safe if they are held in storage for one or two months. These conclusions are based on the studies of Wade and Shere, who showed that in artificially infected cheeses held at 60°C the typhoid bacilli lived for from thirty-four to thirty-six days. Other investigators maintain that the manufacturer of Cheddar cheese cannot depend on the acids or on the antibiotic forces liberated by the ripening process to free his product from disease producing micro organisms. In California the Agricultural Code has been amended to the effect that all cheese sold to the retail trade must be pasteurized or manufactured from milk which has been pasteurized, except cheese which has been allowed to ripen or cure for a minimum of sixty days. As a further protection, all cheeses in California must be labeled as to date, place of manufacture and grade.

Inhalation of Nebulized Solution of Sodium Sulfathiazole in Bronchial Lesions—Applebaum treated 50 patients with infectious bronchial lesions by inhalation of nebulized sulfonamides. These patients had given no adequate response to sedation, expectorants, iodides, bronchodilating

drugs, bronchoscopy, instillation of iodized oil, oral sulfonamides, clearance of upper respiratory tract and vaccines. Each case was selected on the basis of the following criteria: (1) symptoms of cough and expectoration of more than six weeks duration; (2) no response to previous modes of therapy; (3) the presence of a bronchial lesion of bacterial origin. In several instances the noninfectious type of asthma was treated for the purpose of control. A 5 per cent solution of sodium sulfathiazole was placed in a nebulizer and this was connected by a rubber tube to an oxygen tank equipped with a flow meter. A rate of flow of 4 liters per minute was found satisfactory. The patient held the nozzle of the nebulizer between the teeth and breathed with the mouth open for a period of twenty minutes. Treatments were administered three times daily for an average of ten consecutive days. It was determined that approximately 2 cc of the solution was utilized in a single treatment. Definite improvement resulted in 43 of the 50 cases treated. This preliminary survey indicates the promising therapeutic possibility of sulfonamide nebulization in a resistant type of respiratory infection.

Cruevilhier-Baumgarten Syndrome—Armstrong and his associates reviewed in 1942 the data on 52 previously reported cases of Cruevilhier-Baumgarten syndrome and added to the 2 previously described by them a further case which they found in the necropsy protocols of the Los Angeles County Hospital. The term 'Cruevilhier-Baumgarten syndrome' may be applied to a clinical picture of portal hypertension featured by, a loud abdominal murmur and frequently a thrill. From Armstrong's analysis it appears that cases presenting the syndrome and having adequate necropsy descriptions can be divided into two large groups and seven subgroups. One of these categories (gr

1 A) includes 6 cases that fulfil the criteria of Cruveilhier and Baumgarten as instances of congenital patency of the umbilical vein and atrophy of the liver with little or no cirrhosis and splenomegaly. This combination is designated "Cruveilhier-Baumgarten disease" (in contrast with "syndrome"). Any other disease that results in portal hypertension and happens to utilize umbilical collaterals excessively may produce a similar clinical picture, the "Cruveilhier-Baumgarten syndrome." Yater and Kendrick report 2 such cases. The first concerned a woman aged 53, the second a man aged 31. These 2 cases bring the total reported number to 57. One patient is still alive without complaints, the other died but necropsy was refused. Both patients had disease of the liver, probably cirrhosis. The murmur and thrill are most intense in the umbilical or epigastric regions and are generally continuous. The murmur has been described as a venous murmur a hum, a roar, a "mill-like murmur" a hollow spinning wheel sound and a grinding sound. Armstrong states that the production of the murmur probably depends on the passage of blood to an area of different caliber or direction, the eddying of a current in a blind dilated venous sac or pouch, or the flowing of the blood through constrictions in the course of a dilated and tortuous vein. Yater and Kendrick think that the murmur results from the flow of blood from small vessels into large ones in or close to the abdominal wall. For such a situation it is not necessary to assume that patency of the umbilical vein exists. They believe that if care is taken to auscultate the epigastrium in cases of disease of the liver mainly advanced cirrhosis such a murmur will be discovered more often.

Report of New Practice Act C Selby—p 315
Presentation of Oliver Wendell Holmes Trophy R H Loder—p 318

Fluorescence Microscopy in Tuberculosis—Hagemann in 1937 first proposed staining bacteria with fluorescent dyes and examining them with the fluorescence microscope. He discovered that the dye auramine would stain *Mycobacterium tuberculosis* and that the organism, once stained, would resist decolorization in acid alcohol whereas other organisms readily decolorized. The auramine was as specific for acid fast organisms as was fuchsin. The auramine stained bacilli appeared yellow, while the background was black. Tanner showed that this method detected organisms more frequently than did the usual carbolfuchsin method. He noticed, in studying tissue sections with the usual hematoxylin-eosin stain, a small area of granulomatous nature. Sometimes this lesion is so small that additional sections of the same block of tissue may not contain the suspected lesion. In such instances the original hematoxylin-eosin slide can be put in xylene to remove the cover slip. Then the slide is placed in acid alcohol to remove the stain. After allowing the tissue to dry, it can be stained with the fluorescent dye auramine exactly as if this was to be the original stain. The same granulomatous lesion can thus be checked by the fluorescence microscope for the presence of acid fast organisms. The staining by auramine does not interfere with the subsequent staining by fuchsin, and thus a comparison of the number of organisms stained by each method may be made. The author has made such a comparison. By greatly limiting the area of tissue examined and recording on a graph the location of each organism as seen in the examination by each method it has been possible to compare identical fields. More organisms are visible by the auramine fluorescence method and only occasionally does an organism appear with the Ziehl-Neelsen method

that has not been seen with the fluorescence microscope. The author also suggests that the fluorescence method may be of value in studying the pattern of organisms in tissue infected by *Mycobacterium tuberculosis*.

Differential Diagnosis of Weakness and Fatigue—Allan states that one of the problems most frequently encountered by the general practitioner and the internist is a complaint variously described as weakness, exhaustion, fatigue, loss of ambition, low vitality or weak spells. Data have been compiled at the Lahey Clinic on 300 consecutive cases in which weakness, fatigue or weak spells were the chief complaint. Physical disorders were found to be responsible in 20 per cent of the cases, in the others a nervous state was the cause. This state was classified as a neurosis in approximately 20 per cent and as a benign nervous state, chronic nervous exhaustion or nervous fatigue in the rest of the cases. In nearly half of the cases in which a physical disorder was found to be the cause of weakness it was possible to make a positive diagnosis by clinical observation alone. In the others, laboratory tests or roentgenograms were essential to reveal a hidden disease or confirm the diagnosis. The most frequent physical disorders were chronic infection, diabetes, heart disease, various neurologic disorders and serious diseases of the blood. Certain conditions, such as vitamin deficiency and glandular disorders, considered widespread causes of weakness by both the public and the medical profession, were actually found to be rare, and not a single case of weakness due to liver trouble, poor elimination or low blood pressure was encountered. Although a high percentage of patients with weakness or fatigue have no physical disorder, there is a group in which physical conditions of unusual interest may be discovered. In any case these symptoms warrant thorough and complete investigation.

Headaches from Eye Ear, Nose and Throat Standpoint R MacDonald—p 184

Suggested Method of Treatment for Acute and Chronic Infections of Middle Ear R W Hanchel—p 187

Headaches—Headaches related to the eye may be due to errors of refraction, accommodation anomalies, muscle imbalances and glaucoma. Patients with refraction errors complain of burning, stinging and a sandy feeling in the eyes. In glaucoma the headache at first is localized in the eye ball, later it radiates over the entire area supplied by the ophthalmic division of the trigeminal nerve. There is a rare type of ophthalmic migraine which is caused by glare, but this condition has other associated symptoms such as ocular paralysis, particularly that of the third nerve. Retrobulbar neuritis causes pain deep in the orbit and is worse when the eye is in motion. There are headaches caused by orbital tumors and by exophthalmos. Sinus headache is the most popular type of which patients complain. The public has been made sinus conscious and is aided by newspaper advertisements and radio broadcasts. The proprietary drugs advertised contain bromides and acetanilid. When first taken they will usually relieve headaches, but their continued use produces headaches and symptoms of poisoning. Many persons who have sinusitis of long standing never complain of headache, others have sinusitis and headache. The two, however are not necessarily associated, and perhaps 5 per cent of all headaches are due to sinusitis. Maxillary sinus headaches are mostly located in the cheek and zygomatic regions and in the frontal sinus over the eyes. The sphenoidal sinus usually causes temporal and vertex headaches. Infections in the ethmoidal air cells cause pain in behind and in the inner angles of the eye. While patients are under observation, barbiturates with ephedrine will give temporary relief. Many headaches are benefited by thyroid even though the basal metabolic rate is not too low. Unilateral headaches along the branches of the sphenopalatine ganglion have been confused with sinus headaches. Cocainization of this ganglion often leads to dramatic relief. Acute otitis media may cause diffuse dull headaches around the mastoid and deep in the ear. Paracentesis usually relieves them. Where the pain is noted constantly in one area, an extradural abscess should be suspected. Occipital headaches usually point to cerebellar abscess. Headaches, plus diplopia, dysphagia and facial pains due to involvement of the sixth, ninth and fifth cranial nerves may be caused by carcinoma of the nasopharynx.

Perforating Abdominal Injuries—Sloan presents observations on 146 cases of perforating abdominal injuries that were explored at the Johns Hopkins Hospital between 1925 and 1943. There were 91 gunshot wounds and 55 stab wounds. Among the 87 cases explored from 1925 to 1938 there were 27 deaths, a mortality of 31 per cent. Between 1939 and 1943 there were

6 deaths in 59 cases, a mortality of 10.1 per cent. The operative technic remained essentially unchanged. The striking reduction in mortality in the years 1939 to 1943 can be attributed chiefly to the use of transfusions and sulfonamides. Improvements in anesthesia and the use of constant gastric suction or the Miller-Abbott tube would seem to have had only a small share in the reduction in mortality. It is probable that the use of blood and blood substitutes has had a greater influence in the reduction in mortality than the use of sulfonamides despite the fact that most of the deaths in recent years have been due to shock rather than to infection. Patients in shock are more susceptible to infection. The improved postoperative condition of patients receiving transfusions must have played a large part in their resistance to infection. In the perforating abdominal injuries operated on in the past five years death has been due largely to hemorrhage which could not be controlled at operation or to injury so severe that massive transfusions had little effect on the patient's state of shock. The results reviewed here, of patients treated with all the resources of a large hospital, represent a goal unattainable by the military surgeon on the battle field. However, the use of transfusions and sulfonamides can effectively reduce the mortality of perforating abdominal wounds.

Sympathectomy in Buerger's Disease—According to de Takats sympathectomy in Buerger's disease does not modify the course of this disease, it is undertaken only for the purpose of improving circulation in limbs in which blood vessels are occluded. Before sympathectomy is undertaken it is necessary to demonstrate the presence of an adequate collateral vascular bed. The disease must be in a quiescent stage and it should not show too much visceral extension. The author discusses the essential preoperative studies and describes and illustrates surgical procedures and postoperative management. In a series of 50 cases 136 sympathectomies were done. About one half of these patients have also had minor amputations combined with sympathectomy. Of the 50 patients, 37 have been rehabilitated to full time work, 7 are doing part time work and only 6 are invalids. In addition to foot hygiene and complete abstinence from tobacco, a change of occupation is important for those whose feet are continuously subjected to an exposure to cold or trauma.

Hypoproteinemia in Thoracic Surgery—Thornton and his collaborators state that the surgical treatment of disease of the chest may be complicated by hypoproteinemia owing largely to the chronicity of many lung diseases and the relatively severe blood loss associated with major thoracic surgery. They investigated the effect of chest operations on plasma proteins in 32 operations on 29 patients. The operations included 14 lobectomies, 5 pneumectomies, 7 exploratory thoracoplasties, 1 partial pericardectomy and 1 first stage lobectomy. Preoperative plasma protein and hematocrit determinations were made on all patients. During the operations and in the postoperative period large whole blood and plasma transfusions were given to replace blood loss. At two day intervals following operations the plasma proteins and hematocrit determinations were repeated. The study was continued for ten days or until the readings returned to the preoperative level. A plasma protein fall of approximately 1 Gm per hundred cubic centimeters occurred in 31 of the 32 operations. The fall usually occurred from three to five days following operation and was accompanied by a similar decrease in hematocrit, hemoglobin and, to a lesser degree, red blood cells. The principal causes of the drop in plasma protein were (a) diminished protein reserve, (b) operative blood loss, (c) loss of blood and plasma into the wound and pleural space after operation, (d) infection and (e) inadequate replacement. Massive transfusion of whole blood was the most satisfactory single therapeutic agent when the plasma proteins were lowered as the result of hemorrhage.

Maternal Obstetric Paralysis—O'Connell believes that protrusion of a lumbar intervertebral disk is the factor which produces maternal obstetric paralysis in a large proportion of cases. He presents 4 case reports which indicate an increased risk of a lumbar intervertebral disk protrusion occurring in pregnancy. This may be due to changes in the intervertebral joints analogous to those known to occur in the pelvic joints during pregnancy. Such changes would render the joints concerned less fit to withstand normal stresses as well as those

additional stresses occasioned by the posture of pregnancy and by labor. The severe objective neurologic disturbance which not infrequently occurs when a disk protrudes during or after labor may perhaps be accounted for by the large size and the rapid development of the protrusion and the consequent severe involvement of nervous tissue. Changes in the lower intervertebral joints in pregnancy and the puerperium render them less fit to withstand strain. The strains of heavy work appear to be contraindicated at such times. Spontaneous cure of maternal obstetric paralysis frequently occurs, but sometimes recovery is slow and incomplete. Operation will be indicated when the motor disturbance is severe and persistent even if pain is slight. On the other hand, severe sciatic pain which does not respond to rest may indicate operation when objective neurologic disturbance is mild. In cases which fall into either of these groups, treatment by excision of the disk protrusion can be recommended.

Cultivation of *Gonococcus*—Morton and Leberman compared the value of the standard chocolate agar and the chocolate agar with Bacto-Supplement-A (extractives of yeast and crystal violet). The latter medium was found to be more accurate in the detection of gonococci in male urethral discharges.

Cold Agglutination Test in Primary Atypical Pneumonia—According to Heintzelman and Seligmann the physical aspects of primary atypical pneumonia are meager, consisting usually of rales over the affected area. In the more severe cases dyspnea, cyanosis and prostration occur. Diagnosis, particularly in patients with no objective physical findings depends on the x-ray examination. Recently the cold agglutination reaction has been found a promising adjuvant in the diagnosis of this disease. The cold agglutination reaction is based on the presence of agglutinins which cause clumping of homologous or group O red cells at low temperatures. To test for the presence of these agglutinins serial dilutions of serum are mixed with washed suspensions of group O erythrocytes in isotonic solution of sodium chloride. The tubes are allowed to stand overnight in a refrigerator at temperatures varying from 0 to 5 C. Readings are made the next morning. The test is not infallible since cases do not all yield a positive reaction. Furthermore cold agglutinins have been reported in paroxysmal hemoglobinuria, trypanosomiasis, pernicious anemia, leukemia, lymphoblastoma, cirrhosis, venous thrombosis and gangrene among others. When it concurs with the clinical picture of primary atypical pneumonia, the test becomes virtually specific for this disease. The authors employed the cold agglutination test in 33 cases of primary atypical pneumonia which were proved by roentgenoscopy. Twenty-two patients showed a positive titer, that is a cold agglutination reaction in serum dilution of 1/32 or above, at some time during the course of their disease. A positive reaction has considerably more significance than a negative one. In pneumonias of undetermined etiology the detection of cold agglutinins made it possible to cease or

to withhold sulfonamide therapy, as most authors are agreed that primary atypical pneumonia does not respond to this type of treatment. The test was found to be of considerable help in the evaluation of upper lobe lesions. Patients having such lesions frequently require repeated sputum and x-ray studies over long periods of time to establish the presence or absence of pulmonary tuberculosis.

Passage of Miller-Abbott Tube Through Pylorus with Aid of Electromagnet—Mayer points out that the Miller-Abbott tube has not been as widely used as it should be because of the difficulty in getting the tip past the pylorus. Several methods have been suggested to overcome this difficulty, and in 1933 Paine suggested the use of an electromagnet. The author recently attempted to use a magnet after having failed two years ago. He found that alnico, a permanent magnetic alloy satisfied the demand for a highly magnetic relatively noncorrosive tip. The metallic tip is fixed on the end of an ordinary Miller-Abbott tube. This is used in conjunction with an electromagnet. In all cases in which alnico is used the polarity of the tip of the tube must be determined with relation to the magnet the latter being adjusted so that it attracts rather than repels the metallic tip. This can easily be tested prior to introduction of the tube, and if the tip is repelled by the electromagnet the polarity of the latter can be reversed by reversing the plug in the socket. The tube is passed through the nares into the stomach. After the stomach has been decompressed by attachment of a Wangenstein suction apparatus the tube is passed down to the pylorus. Occasionally the tube will tend to loop back in the stomach, and the magnet in these cases can be applied under fluoroscopic control along the anterior abdominal wall in such a way as to guide the tip toward the pyloric antrum. Once the tip has reached the pylorus the patient is turned to the right anterior oblique position (either erect or prone) and the magnet applied firmly against the right flank posteriorly in line with the general direction of the first portion of the duodenum and at the same level as the tip of the tube as visualized under the fluoroscope. The power is then turned on and the tube slowly but steadily advanced from above. It will be seen under the fluoroscope to pass quite readily through the pylorus into the first portion of the duodenum. The magnet is then removed the tube advanced and the balloon inflated in the usual manner. The author used this method in a small number of cases, the results are promising in that the tube can usually be passed through the pylorus within one or two minutes and in no case has it failed.

"Suture" of Wounds by Plasma-Thrombin Adhesion—Young and Favata show that adherence of wound edges or surfaces can be readily accomplished by the use of plasma and purified thrombin. The fibrin fixation artificially produced in this way has less tensile strength than ordinary suture material, for this reason use of plasma-thrombin adhesion of wounds should be limited to those in which tension does not exist. Plasma-thrombin adhesion has been found useful as the sole fixation (1) for traumatic lacerations, (2) as a skin closure when a particularly fine scar is desired, (3) as a method of producing adhesion between the flaps and the chest wall in radical mastectomy and (4) as an adjunct in free skin graft. No untoward results have been observed in 69 cases in which plasma-thrombin adhesion of wounds has been used.

Tumors of Thyroid Produced by 2-Acetyl-Amino-Fluorene and Allyl-Thiourea—Bielschowsky demonstrated that tumors can be induced in white rats by 2-acetyl-amino-fluorene. Tumors did not develop in endocrine glands. This seemed to indicate that these cells are far less susceptible to the carcinogenic action of the drug than the epithelial cells of many other organs, such as the liver or the mammary gland. From human pathology it is known that cancer of the thyroid nearly always originates in a goitrous gland. Since goiter can be easily produced in rodents, the best experimental approach to the problem at hand seemed to investigate the action of the carcinogenic agent on a goitrous thyroid gland. Acetyl-amino-fluorene was given as in previous experiments at a daily dose of 4 mg per rat for thirty weeks. The rats received daily 5 mg of allyl-thiourea each for the first four weeks and then 6 mg daily until the animals were killed. Twenty rats were used. Ten received the standard diet with the addition of acetyl-amino-fluorene and allyl-thiourea. 10 served as controls and received the same diet with the addition of allyl-thiourea only. Benign and malignant tumors of the thyroid were produced in the thyroid by the combined action of allyl-thiourea and 2-acetyl-amino-fluorene. Neither drug when given alone induces neoplastic growth in the thyroid gland of the white rat. Prolonged administration of allyl-thiourea produces only a parenchymatous solid goiter. 2-acetyl-amino-fluorene does not affect normal thyroid tissue at all. The stimulated hyperplastic thyroid is, however, susceptible to the carcinogenic action of acetyl-amino-fluorene.

Roentgenographic Investigation of Pelves of 1,000 Pregnant Women—Kenny examined by x-rays the pelvis of 1,000 women in whom clinical examination in late pregnancy or history of previous dystocia presaged abnormal labor. Women were selected for roentgenography nearly always in the last two weeks of pregnancy. The conviction was reached of the importance of the shape rather than the size of the pelvis as a guide to prognosis and conduct of labor. Thus normal delivery has been achieved with a simple flat pelvis with a true conjugate of the brim of $3\frac{1}{2}$ inches and cesarean section found necessary with android pelvis of $7\frac{1}{2}$ inches conjugate. The 1,000 roentgenograms cover the greater number of the 520 operative deliveries that were carried out. With increasing experience it became possible to forecast the course and nature of labor and delivery very accurately from the shape of the pelvis, the rela-

tive position of the fetal head and a study of the maternal powers to endure the proposed travail. A survey of the bony structures of the birth canal and its passenger evaluates the few factors that can be measured with scientific accuracy and it should form at least the basis on which "suspect" cases may be safely treated. The various pelvic types in this clinically suspect group are classified morphologically according to the Caldwell-Moloy classification, except that the author has substituted the term "pithecoïd" for "anthropoid." The incidence of the gynecoid, android, pithecoïd and platypelloïd combinations of these and pathologic types such as rachitic flat and osteomalacic ones are listed in a table. Taking the gynecoid pelvis as unity, the possessors of android pelvis are more than twelve times more likely to develop the mild and eight times more probably the severe forms of toxemia. Puerperal morbidity likewise is greatest in those with android and android-gynecoid pelvis. The author also inquired into the similarity between the pelvis of female infants and their mother. Of 20 little girls examined in this respect, 13 had pelvis of exactly the same type as their mothers. The author urges the use of roentgenographic methods of estimating pelvic capacity in the interests of mother, child and accoucheur.

Hepatitis After Yellow Fever Inoculation—Findlay and his associates say that the presence in endemic yellow fever zones in Africa of considerable numbers of Europeans as well as of Africans made it important to detect yellow fever at the earliest moment for, even though wholesale prophylactic inoculation had largely allayed anxiety, there was always the hazard that a few might have escaped immunization. In this African command every case of jaundice in military personnel has been notified whatever the presumed cause. It has thus been possible to get an idea of the incidence of infective hepatitis month by month. Late in December 1942 the notifications for jaundice began to rise rapidly. As the notifications continued to increase in January it was found that the cases followed injection of particular batches of yellow fever vaccine used between Sept 19 and Dec 31, 1942. In all 689 cases were recorded as being due to yellow fever vaccine inoculations. The average latent period among 670 cases in which the date of commencement of symptoms could be recorded was one hundred and one days. Preicteric symptoms were in the main visceral. Loss of appetite, nausea, lassitude and vague abdominal discomfort were the usual complaints though occasionally the abdominal pain was severe enough to suggest biliary colic or duodenal ulceration. The physical signs were jaundice, hepatic and splenic enlargement,

The existing gap in physical therapy appear to be due to
various causes: (1) to certain limitations of the Swedish system
on which British physical therapy is grounded, (2) to an old
prejudice against apparatus, (3) to the lack of that class of
work designated as "self activated." One of the chief limita-

tions of the Swedish system is that the operator tends to work
on rather than with the patient. One may expect, therefore, to
see the pendulum swing sharply in the direction of hard exercise.
Such work will take the form of outdoor occupations games.
ent careful
physical training of a stre-
muscle training against
work has been the in-
of electrical thou-
it into

therapy, while continuing on the old sound basis, now incor-
porates new methods so as to fit in with a more strenuous type
of work required by the modern conception of rehabilitation.
Simple appliances and rhythmic movement and also have the
advantage of assisting relaxation, especially that reciprocal
relaxation of the antagonist muscles which is so important after
traumatism. Apart from these factors there is the underlying
aspect of increased self respect and improvement in morale
which comes to patients who feel that they are cooperating in
their treatment and consequently a stirring up of hope, of better
health which will promote better functioning.

A number of distinguished men and women have contributed
chapters on their specialties, thus enabling the scope of modern
physical therapy to be presented in a way which would have
been impossible for a single writer to express. Dr J B Memell
is given special consideration for his chapter on manipulations.
Physical therapists are greatly indebted to him for his brilliant
work. Mr Gerald Rae Fraser presents some interesting photo-
graphs for "massage." The supplementary chapters on joint
manipulation, recovery after fractures, rehabilitation methods
in chest and maternity cases, electrical treatment and occupa-
tional therapy, all written by colleagues distinguished in their
particular subjects, add greatly to the value of the book and
make it a complete textbook on the subject. This book is of
real value to all physical therapists, to all orthopedic and trau-
matic surgeons and especially to military surgeons.

Hipertensión arterial nefrótica Por Eduardo Braun Menéndez y otros
Cloth Pp 475 with 93 illustrations Buenos Aires Librería y Editorial
"El Ateneo," 1943

The authors are distinguished contributors to the study of
renal hypertension. As the title indicates, the survey is prin-
cipally concerned with this topic, although discussions of other
modes of experimental hypertension and of clinical hyperten-
sion are included. The book is completed by an extensive and
excellent bibliography, an index and an appendix which details
the special biochemical methods used in their own investigations.

The authors state in the introduction that "in evaluating
results, which are sometimes contradictory, we have taken into
account, apart from the proof—which is the essential—the
authority of those who present it, as manifest in their scien-
tific status and training, their critical spirit and honesty." The
concept, however it may be justified as continental or Latin
introduces elements of personal appraisal which are too danger-
ously subjective to form a part of international scientific method.
It leads the authors magisterially to toss the stones of distrust
at others, unaware that the mansions of every one's science,
including their own, have occasional panes of glass. It flows
from this that the book heaves zealously to the authors' stream
of conviction, discarding in the chapter summaries what does
not fit their personal measure.

Thus, their data do not establish the presence of pressor sub-
stances of renal origin in the blood in long established renal
hypertension, were such substances present, it is far from estab-
lished by their citations that these are liberated as the result
of renal ischemia. Still, it is stated that "experimentation

has proven that it [renal hypertension] is due to libera-
tion of pressor substances of ischemic origin" (p 248) and the
question is begged again in the chapter heading "Renal Hyper-
tension Due to Renal Ischemia."

Studies are quoted which prove that while renal arteriolar
sclerosis is common in the late and fatal stages of hypertension
it is not nearly as common in earlier stages of the disease, but
the authors state that "it is now accepted that in essential hyper-
tension there exists from the outset a certain degree of renal
arteriolar sclerosis," fitting the conclusion to their concept but
not to their evidence. Minor inaccuracies occur in the review

unction, thus, it is not true that glomerular filtration
ows the levels of arterial tension (p 43)
t arteriolar constriction must always
above the normal (p 45). The
hypertensive animals to a variety
established fact" (hoche seguro)
ble observation. The "stangs
failure is attributed to renal
ia with release of humoral
functionally independent of

abdominal tenderness and fever. There was one death in the series. No features of the clinical history or the necropsy served to distinguish this case from the findings in infective hepatitis; the terminal rise in temperature especially is characteristic of what has been seen in fatal cases of infective hepatitis. On the basis of necropsy studies in this case the authors say that both the macroscopic and the microscopic findings point to the conclusion that death was due to a progressive and overwhelming destruction of the liver parenchyma. Treatment has been along routine lines. In mild cases additional sugar has been given by mouth, in severe cases intravenous drips of 10 per cent glucose-saline solution have been used, together with 5 to 10 units of insulin a day. Up to 20 Gm of fat was allowed a day in some cases together with small daily doses of sodium taurocholate, to assist in the absorption of vitamin K. In 2 cases with purpuric rashes vitamin K was administered with apparently beneficial results. Later, additional protein has been added to the diet in the form of skimmed milk up to 1½ pints daily, eggs and a puree of liver. In convalescence dried yeast has been prescribed.

Cardiac Neurosis as Manifestation of Hypoglycemia—Greene reports that 5 patients were admitted to the hospital with the diagnosis of effort syndrome. Each patient had symptoms suggesting a cardiac abnormality, and each had a normal heart. The symptoms of the 5 patients were found to be related to hypoglycemia. The early symptoms of hypoglycemia are in reality those of excessive epinephrine secretion. Da Costa's syndrome is caused by abnormal fears. The somatic symptoms of fear are also due to excessive epinephrine secretion. It is therefore not surprising that the symptoms of hypoglycemia and of Da Costa's or effort syndrome are identical. Since the symptoms of the former can be relieved by a suitable diet, an effort should be made to evaluate the part played by abnormal carbohydrate metabolism in producing the symptoms of patients with Da Costa's syndrome or a similar cardiac neurosis.

*Evaluation of Sulfonamide Therapy in Trachoma. L. Poleff—p. 156

Sulfonamide Therapy in Trachoma—Poleff, on the basis of observations on 1,050 trachoma patients, regards sulfonamide therapy not as a panacea but as an important adjuvant. Sulfonamide therapy will effect complete cure of trachoma only in combination with local treatment, he says. Following microscopic examination of secretions and of epithelial smears, a disinfecting treatment with silver nitrate solution or a disinfectant solution is employed for about a week. Then follows pressing out of the follicles and scraping of the diseased conjunctiva. After the irritative reaction caused by this has subsided, conjunctival massage is begun. This massage by means of a glass or silver rod must be continued for months. During

all this time the patient is given sulfonamides internally. The duration of trachoma treatment averages three months. The internal sulfonamide therapy exerts a favorable influence on the secondary processes, particularly the catarrhs and corneal ulcers. During the early stage the sulfonamides act favorably also on the trachomatous follicles. Sulfonamide therapy sterilizes the trachoma infection and thus provides protection against relapses.

*Etiology and Pathogenesis of Erythroblastosis of Newborn Infants. M. Pereira de Mesquita and V. R. Leite Ribeiro—p. 85

Etiology and Pathogenesis of Erythroblastosis Fetalis—Three factors are necessary for the development of erythroblastosis of newborn infants: (1) A fetus with a positive Rh blood factor, whereas the mother has a negative Rh blood factor, (2) an interchange of fetal Rh erythrocytes and maternal anti-Rh agglutinins through the placental barrier, and (3) lack of group specific substances (in the placenta, the umbilical cord and the fetus) which may be able to fix and neutralize the maternal agglutinins. The first and last conditions have been proved. The passage of erythrocytes through the placenta has not been proved. The authors made daily intraperitoneal injections of dissolved erythrocytes in amounts corresponding to 1 cc of the total blood of Rhesus monkeys for eleven consecutive days and five injections of the same dose every other day. Specific agglutinins appeared in the blood of all the guinea pigs as proved by the occurrence of agglutination of the erythrocytes which was equal to that which is observed after experimental immunization of guinea pigs with blood of Rhesus monkeys. The authors conclude that the stroma of erythrocytes of the fetus rather than the erythrocytes is the causal factor of the immunization of mothers and of the consequent formation of anti-Rh agglutinins by the mother and also the cause of the development of erythroblastosis in the fetus.

*Osteomyelitis of Frontal Bone. I. Otte—p. 4
Cancer of Esophagus. H. Garcia—p. 29

Osteomyelitis of Frontal Bone—Otte reports 12 cases of chronic and acute forms of the disease. General and local infection and trauma may play a causal role. The symptoms are those of acute infection with fever, local pain and edema. The acute stage is followed by a period of complete subsidence of the symptoms, which lasts for several months. Palpebral edema, which in some cases simulates allergic edema, appears and disappears at varied intervals of weeks during the period of subsidence of the symptoms. It is a diagnostic sign of chronic frontal osteomyelitis and an indication for x-ray study of the frontal bone. Operation consists in resection of the necrotic bone and drainage. Delayed operation is the cause of the development of either a Pott's puffy tumor or a cerebral abscess. Acute frontal bone osteomyelitis is a complication of chronic suppurative sinusitis. It can be prevented by surgical removal of the outer and inner tables of the frontal sinus in cases of chronic suppurative sinusitis. The therapy consists in radical resection of the frontal bone as advocated by Mosher. Sulfonamide and blood transfusions are indicated before the operation in cases of hematogenous type.

Strophanthin Therapy of Fresh Cardiac Infarction—Edens states that the indirect effect of strophanthin on the functional disturbances of the coronary arteries results in the improvement of the coronary circulation and the cardiac metabo-

lism In the majority of the cases this indirect effect compensates for its immediate unfavorable effect, such as auricular fibrillation, bigeminy and auricular tachycardia for which the abnormal irritability of the impaired cardiac elements may be responsible. The rationale of strophanthin therapy was demonstrated in 24 cases of cardiac infarction. Treatment was instituted within the first six days of the attack. There were 20 men and 4 women. Seven patients were between the ages of 40 and 50 years, 5 from 50 to 60 years and 12 patients were over 60. Eleven patients had hypertension. Strophanthin alone was administered in 13 cases. Strophanthin combined with half an ampule of theophylline and oxyamine or with 1 mg of dihydromorphinone hydrochloride or with both was employed in 11 cases. Strophanthin was given in doses of 0.1 to 0.3 mg. Sedatives were given three to four times daily. Seven patients died within two to sixty-five days, 1 died after two years and 1 after two and a half years. The condition of the other 15 patients was improved considerably. All the patients experienced immediate relief from the administration of the strophanthin alone and particularly after the combined strophanthin-dihydromorphinone therapy. There was not a single fatal case due to strophanthin, since death did not occur within the first hour after its administration. Clinical experience proved that one hour is required to compensate for the immediate unfavorable effect of the drug.

Etiology of Epidemic Hepatitis—Siede and Lutz state that epidemic hepatitis is a contagious disease whose epidemiologic behavior and characteristic clinical picture suggest a specific causative agent. Human duodenal juice was used as an inoculation medium in experiments following Woodruff and Buddingh's chorioallantois cultivation method. Twenty-one specimens of duodenal juice from persons suffering with epidemic hepatitis and 5 specimens from normal persons were inoculated into large chicken eggs. Not a single embryo died from every 8 eggs which were inoculated with 1 of 3 of the 5 specimens from normal persons. One embryo died from every 8 eggs which were inoculated with 1 of the remaining 2 specimens from normal persons. Chorion and liver pulp from these dead embryos were inoculated into two series of 8 eggs, and every 1 of these eggs hatched. Results of inoculation experiments with the 21 specimens from persons suffering with epidemic hepatitis were as follows. All the eggs inoculated with 7 of the specimens hatched. In 4 additional instances many of the embryos died but cultivation of the causative agent by passage failed. Passage was performed successfully with the remaining 10 specimens. An agent was isolated from the duodenal juice, which according to its biologic behavior, may be classified with the filtrable types of viruses. Its cultivation depends on early duodenal removal within the first days of the disease and on immediate inoculation avoiding prolonged transportation from the residence of the patient to the place where the inoculation is performed or on using a frigidaire for the transportation. Chicken embryos died within five days on an average. Time of death varied from three to nine days, depending on the virulence of the agent. Occasionally full virulence may be maintained for from six to eight passages, but on an average it may disappear after the fourth passage. The virus seems to be hepatotropic, since the passage was particularly successful when the liver pulp of the dead embryos was used. Its stability is suggested by the fact that in the frigidaire the virus in the duodenal juice may be preserved for fourteen days, and in the embryonal tissues it may be preserved for eight days. Thermolability, however, is suggested by the fact that questionable or negative results were obtained with specimens kept for some time at a temperature of $+20^{\circ}\text{C}$.

Artificial Hypoprothrombinemia and Its Therapeutic Application—Von Kaulla states that thrombosis may be prevented by prolonging artificially the coagulation time of the blood. That may be obtained by a reduction of the prothrombin

level since prothrombin represents an integral factor in intravascular clotting. Experiments on rabbits and on normal men with dicumarol are reported. The prothrombin content of the blood was determined by Lehmann's modification of Quick's method. Five mg of the compound per kilogram of body weight was administered to rabbits by stomach tube. The compound acts only after six to ten hours and even later. Its effect, however, is intensive and may last for six days, whereas massive doses of heparin (125 mg per kilogram) had only a momentary effect. Intravenous administration of massive doses of vitamin K (30 mg per kilogram of body weight) did not counteract the effect of dicumarol. Doses of from 125 to 375 mg of 'anti-prothrombin,' a Swedish commercial preparation of dicumarol in tablet form, were administered to healthy men. The effect on the prothrombin level was significant. The compound acted at an interval of from six to ten hours, but its effect was prolonged for from seventy-two to one hundred and twenty hours. An increase in prothrombin for from twelve to fourteen hours resulted in several instances from oral administration of from 100 to 200 mg of vitamin K but was followed again by a sudden reduction of the prothrombin, which was compensated for later on. This increase in the prothrombin level occurred at an interval of from three to ten hours after the administration of vitamin K. Untoward reactions such as vomiting or diarrhea, abdominal pain associated with rise in temperature and acceleration of pulse for several hours occurred within two hours after the administration of 'antiprothrombin.' The administration of from two to three single doses of 125 mg after meals may reduce these untoward reactions. Eleven other coumarin derivatives were tested on rabbits, but the duration and the intensity of their effects did not equal those of anti-prothrombin.

Leukopenia After Heparin Administration—According to Jucker, leukopenia occurred in both rabbits and man after intravenous injection of heparin. The reduction in the number of leukocytes was manifest within three to four minutes. The polymorphonuclears were more affected than the lymphocytes. In the majority of the cases the initial number of leukocytes recurred within six to ten minutes, but leukocytosis may occur occasionally. The leukopenia which resulted in the rabbits from the rapid administration of large doses was more severe than that from the slow administration of smaller doses or from the slow administration of equal doses. The increase in the number of leukocytes recurred independently from the absolute amount of the administered preparation. It is suggested that this phenomenon is the same as that observed after the administration of other high molecular bodies such as glycogen, acacia, gelatin, methyl cellulose, albumin or peptone. The author mentions the theory of Fahraeus and Vajons, according to which reduction of the suspension stability of the blood is the cause of leukopenia. The leukopenia produced in man was less severe than that in rabbits and resulted from such small doses of heparin as 0.12 mg per kilogram of body weight. There were no allergic reactions when pure heparin preparations were employed. The drop in blood pressure was not pronounced (about 5 mm of mercury). Heparin should not be given to blood donors in cases in which transfusion aims to increase the defensive power and the volume of the circulating blood or to combat anemia. Administration of heparin is not advisable in cases of agranulocytosis. It may be safe to proceed with blood transfusion after the heparin treatment when the leukocytes have once more risen to safe levels. Heparin treatment is contraindicated in patients with deficient leukopoiesis.

Book Notices

Rehabilitation Re Education and Remedial Exercises By Olive F. Guthrie Smith MBE CSMVG TNG Principal of the Swedish Institute London With a foreword by Lord Horder G C V O M D F R C P Cloth Price \$6 Pp 424 with 273 illustrations Baltimore William Wood & Company 1943

Reconditioning and rehabilitation are rapidly becoming established as scientific branches of medicine. The main objective of the book is to draw attention to the extraordinary value of reeducating joints and muscles that have been incapacitated through injury or disease by movement when the action of gravity has been eliminated. Exercises of joints should encourage the patient to cooperate in his own cure. The movements are performed entirely by the patient himself, but under the supervision of a skilled operator.

Rehabilitation covers the whole range of treatment of the injured person from the time of accident to the point at which his condition is restored to the pre-accident state, or until the fullest possible restoration has been effected. One of the first steps in rehabilitation is to awaken the will to recover and to obtain cooperation. From the first day in the hospital the patient's mind is turned toward improvement. Unless absolute rest is necessary he is called on to exert a conscious effort on his own behalf every day. His interest in inducing the return of power by his own perseverance must be stimulated and encouraged. After the cooperation of the patient has been obtained, his actual treatment will be the sum total of the coordinated activity of a team of experts, medical and physical therapeutic, whose work will not end until he is fit for discharge and normal work. The physical therapist's part in this coordinated plan is ever enlarging in scope. In recent years its growth has acquired tremendous momentum. Thus muscular activity carefully graded to suit each stage of recovery is the basis of the physical therapist's contribution to rehabilitation. Every new activity is a point gained, and it is by the accumulation of such points that progress is made.

In this book will be found a series of rehabilitation exercises and methods for the reeducation of muscles which have lost some or all of their function. The methods described have been adopted by the ever increasing number of rehabilitation departments in the Ministry of Health as well as by the larger teaching hospitals. Treatment is based on a combination of three principles—psychologic, physiologic and mechanical, each requiring a definite technic. Although apparatus is extensively used, it is recommended that its use remain individual and that the exercises not be allowed to degenerate into mechanical movements. Active movement carried out under supervision is the only safe treatment for recent injuries. It is only by voluntary movement that restoration of function can be achieved. This is true also when dealing with advanced rehabilitation exercises; these must be carried out under voluntary power, the muscles acting against resistances which are continually graduated in strength. Strenuous exercises can be disguised in many ways as games or some useful occupation, such as digging or chopping wood.

The existing gaps in physical therapy appear to be due to various causes: (1) to certain limitations of the Swedish system on which British physical therapy is grounded; (2) to an old prejudice against "apparatus"; (3) to the lack of that class of work designated as "self activated." One of the chief limitations of the Swedish system is that the operator tends to work on, rather than with, the patient. One may expect, therefore, to see the pendulum swing sharply in the direction of hard exercise. Such work will take the form of outdoor occupations, games, physical training of a strenuous type and persistent careful muscle training against resistances. Lack of "self-activated" work has been the most serious gap for two decades. A wave of electrical thought and apparatus swamped active work and forced it into a secondary place, thus it has come about that the usual practice has been to combine massage and electricity and to add a few exercises to complete the treatment. A reorientation is taking place and the emphasis is now on progressive activity rather than passivity while making full use of combined treatments and all the valuable electrotherapeutic knowledge that has been acquired. The training in physical

therapy, while continuing on the old sound basis, now incorporates new methods so as to fit in with a more strenuous type of work required by the modern conception of rehabilitation. Simple appliances aid rhythmic movement and also have the advantage of assisting relaxation, especially that reciprocal relaxation of the antagonist muscles which is so important after traumatism. Apart from these factors there is the underlying aspect of increased self respect and improvement in morale which comes to patients who feel that they are cooperating in their treatment and consequently a stirring up of hope, of better health, which will promote better functioning.

A number of distinguished men and women have contributed chapters on their specialties, thus enabling the scope of modern physical therapy to be presented in a way which would have been impossible for a single writer to express. Dr J. B. Mennell is given special consideration for his chapter on manipulations. Physical therapists are greatly indebted to him for his brilliant work. Mr. Gerald Rae Fraser presents some interesting photographs for "massage." The supplementary chapters on joint manipulation, recovery after fractures, rehabilitation methods in chest and maternity cases, electrical treatment and occupational therapy, all written by colleagues distinguished in their particular subjects, add greatly to the value of the book and make it a complete textbook on the subject. This book is of real value to all physical therapists, to all orthopedic and traumatic surgeons and especially to military surgeons.

Hipertensión arterial nefrótica Por Eduardo Braun Menéndez y otros. Cloth Pp 475 with 93 illustrations. Buenos Aires: Librería y Editorial El Ateneo 1943.

The authors are distinguished contributors to the study of renal hypertension. As the title indicates, the survey is principally concerned with this topic, although discussions of other modes of experimental hypertension and of clinical hypertension are included. The book is completed by an extensive and excellent bibliography, an index and an appendix which details the special biochemical methods used in their own investigations.

The authors state in the introduction that "in evaluating results, which are sometimes contradictory, we have taken into account, apart from the proof—which is the essential—the authority of those who present it, as manifest in their scientific status and training, their critical spirit and honesty." The concept, however it may be justified as continental or Latin, introduces elements of personal appraisal which are too dangerously subjective to form a part of international scientific method. It leads the authors magisterially to toss the stones of distrust at others, unaware that the mansions of every one's science, including their own, have occasional panes of glass. It flows from this that the book hews zealously to the authors' stream of conviction, discarding in the chapter summaries what does not fit their personal measure.

Thus, their data do not establish the presence of pressor substances of renal origin in the blood in long established renal hypertension; were such substances present, it is far from established by their citations that these are liberated as the result of renal ischemia. Still, it is stated that "experimentation has proven that it [renal hypertension] is due to liberation of pressor substances of ischemic origin" (p. 248) and the question is begged again in the chapter heading "Renal Hypertension Due to Renal Ischemia."

Studies are quoted which prove that while renal arteriolar sclerosis is common in the late and fatal stages of hypertension it is not nearly as common in earlier stages of the disease, but the authors state that "it is now accepted that in essential hypertension there exists from the outset a certain degree of renal arteriolar sclerosis," fitting the conclusion to their concept but not to their evidence. Minor inaccuracies occur in the review of renal function; thus, it is not true that glomerular filtration pressure necessarily follows the levels of arterial tension (p. 43) or that glomerular efferent arteriolar constriction must always increase filtration fraction above the normal (p. 45). The increased sensitivity of renal hypertensive animals to a variety of pressor drugs is not "an established fact" (*hecho seguro*) (p. 58) but rather a very variable observation. The "staugs-hochdruck" of congestive heart failure is attributed to renal venous stasis and resultant ischemia with release of humoral pressor agents (p. 286) which are functionally independent of

the nervous system. This view is not reconciled with the claim that renal denervation abolishes hypertension due to experimental renal venous compression (p. 77).

The clinical discussion is weakened by the suggestion that acute glomerulonephritis is a state of acute febrile infection and by a tabular comparison of clinical, essential and experimental renal hypertension, which overemphasizes their similarities as in its suggestion that the response to thoracolumbar sympathectomy is equally insignificant in the two conditions.

This is a useful manual of reference or bibliography for those students of hypertension who are not content with what must still remain arbitrary opinions. Others may be misled by the force and clarity of the highly specific presentation. The authors deserve more than ordinary commendation for their splendid experimental work. The manner they have chosen for its monographic presentation does not do it justice.

Rorschach's Test: I. Basic Processes. By Samuel J. Beck, Ph.D., Head of Psychology Laboratory, Department of Neuropsychiatry, Michael Reese Hospital, Chicago. Foreword by Willard L. Valentine, Ph.D., Head of Department of Psychology, Northwestern University, Evanston and Chicago. Cloth. Price \$3.50. Pp. 223 with 10 illustrations. New York: Grune & Stratton, 1944.

This volume, which is to be followed shortly by a second one by Dr. Beck covering interpretation problems, presents a lucid, specific analysis of the way in which individual Rorschach responses are evaluated or "scored." The literature to date on the Rorschach method has been notably deficient in providing sufficient standards to make the use of this personality test truly objective and scientific. The lack of norms established from accumulated data has necessitated every worker to form his own standards from his particular experience and the theoretical considerations described by the leaders in the field. Thus there was much room for variation in the scoring process basic to the personality interpretation. After employing scientific experimental procedure Dr. Beck has written a technical manual replete with countless examples showing how the psychological determinants of Rorschach responses are decided and their relative weight. A frame of reference is established for the accuracy of form perception and there are detailed descriptions of various types of movement, color and light determined responses. One of the unique contributions of this book is the chapter on the organization activity, wherein the author places a relatively unexplored significant mental process on a statistical basis. This manual should enable much wider use of the Rorschach test as it can be understood by beginners. It likewise can be utilized as a reference book for experienced testers and fulfils a concrete need.

Photomicrography in Theory and Practice. By Charles Patten Shillaber. Cloth. Price \$10. Pp. 773 with 291 illustrations. New York: John Wiley & Sons, Inc. London: Chapman & Hall Ltd. 1944.

This volume can be included in the few authoritative books on photomicrography. The subject is discussed in simple phraseology, and wherever possible diagrams or photographs are used to illustrate a given point more clearly. Several excellent examples of photomicrography are found throughout the text. Chapter 1 deals with the mechanics of the microscope, a clear understanding of which is so essential to successful photomicrography. Other chapters deal with adjustments and various techniques relating to the microscope and the illuminating system, the preparation of the specimen, camera photographic technique and other aspects. Of especial value to the teacher of this subject is the list of practical questions which follow all but two chapters.

It is a matter of regret that a chapter on color photomicrography was not included in this volume since in recent years there has been such great improvement in color photographic processes. The author acknowledges the omission of a consideration of this field as well as of work with polarized light, ultraviolet and infra-red radiation, stereoscopic pictures and other highly specialized fields and promises to amend by adding "from time to time complete information regarding these and other important branches of microscopy." Truly the material in this book is basic and in many instances can be applied to the specialized fields, however, more specific treatment is desirable and the promised chapters will be of great value especially to the research physician and the biologist.

Tuberculosis of the Ear, Nose and Throat, Including the Larynx, Trachea and the Bronchi. By Mervin C. Myerson, M.D., Cloth. Price \$7.50. Pp. 291 with 88 illustrations. Springfield, Illinois: C. Baltimore Charles C. Thomas, 1944.

Unless attached to a hospital for the care of tuberculosis the average laryngologist only infrequently sees the manifestations of this disease. These nevertheless exist and must be constantly kept in mind. The author has had a large experience, and out of a rich clinical background has come this book. It reads easily, much of what has been accepted as fact and passed down through generations of authors is quietly discarded and there appears as a result the seasoned and considered opinion of a careful and competent observer. As is to be expected, tuberculosis of the larynx receives most of the author's attention. To it he devotes seven chapters, representing about one half of the printed matter of his work. The format is such that headings easily appreciated by the eye introduce the reader to the material presented. The author's own statistics from an obviously adequate experience substantiate his statements and there are enough illustrations, all of them apparently new. There follow chapters on tuberculosis of the ear, nose and throat and among others, what is most interesting, a chapter on bronchoscopy in tuberculosis, a field in which the writer has had a great interest. The refreshing candor, the sane clinical attitude and the modesty of presentation of his material by the author recommend this volume to all those who may meet tuberculosis in the special field with which it deals.

Regional Analgesia. By H. W. L. Molesworth, F.R.C.S., Senior Surgeon, Royal Victoria Hospital, Folkestone. Cloth. Price 8s. 6d. Pp. 90 with 42 illustrations. London: H. K. Lewis & Co. Ltd. 1944.

The author bases the contents of his book on experience with regional anesthesia in 1,500 cases. In 500 of these cases major operations were performed. It is clear to the experienced person that the author has intelligently interpreted the actions and reactions observed during use of local anesthetics and that his statements and deductions are accurate and certainly will be unlikely to change even though his experience has been ten times as great except in the case of nupercaine. The attention of the anesthetists in the United States might well be called to the author's suggestion that it should not be necessary for the surgeon to have to carry out the local and regional methods of anesthesia in cases in which regional anesthesia is unsatisfactory and general anesthesia must be resorted to; it is especially undesirable. The text is well illustrated and the methods which the author has found to be valuable include surface analgesia, infiltration anesthesia and a variety of nerve blocks including paravertebral sacral infiltration of hematoma in a fractured bone block anesthesia of the various parts of the extremities, brachial plexus block and various blocks of the cranial nerves. He emphasizes the use of regional anesthesia for operations on the abdominal wall within the abdominal cavity and on the perineum. He devotes five pages to spinal anesthesia. The small size of the book in no way indicates the breadth of treatment of the subject given by the author. This book will be of interest to both surgeon and anesthetist, especially those in England.

Emergency Surgery. By Hamilton Bailey, F.R.C.S., Surgeon, Royal Northern Hospital, London. Fifth edition. Cloth. Price \$18. Pp. 969 with 1,039 illustrations. Baltimore: William Wood & Company, 1944.

This edition is similar to the fourth edition in general plan and setup but has the advantage of containing references to recent developments, notably the sulfonamide drugs and war experience. As was said in a previous review, the prime quality of the book is its practicability. In that respect it should be particularly valuable as a guide to general practitioners who are called on to do emergency surgery. The introduction to this edition is an interesting account of the growth of the book from the first time the author thought of writing it until its final publication. The introduction tells why it is that the reviewer can enthusiastically recommend the procedures outlined as safe, well tried procedures—not always the most recently advocated but those which experience has found useful and which should not be discarded until much time has found the newer ones better.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MINERAL OIL IN INTESTINE

To the Editor—Is it possible for mineral oil to get through the intestine without some of it being emulsified and saponified? Can it escape some saponification in the intestinal and hepatic alkaline secretions? Would not such soap solution be an irritation and in time sclerose the mucous membrane?

M. D. Wyoming

ANSWER—Mineral oil (liquid petrolatum) cannot undergo saponification. Mineral oil is a mixture of hydrocarbons containing only hydrogen and carbon. Fats and fatty oils undergo saponification. Soaps are the alkaline salts of fats or fatty oils. Fats and fatty oils are glycerides or a combination of glycerol and fatty acids. Vegetable and animal oils are natural mixtures of various fats and fatty oils. Their resemblance to mineral oil is in their physical properties, such as consistency and unctuousness.

Mineral oil does undergo emulsification with the water of the gastrointestinal contents. This emulsification by its capacity for holding water and preventing its absorption from the colon and the dilution of the intestinal contents by the oil itself are the physical means by which mineral oil keeps the constipated stool soft.

The use of mineral oil as a laxative does have objections. It interferes with the absorption of fat soluble vitamins. In doses sufficient to make the feces mushy or liquid the intestinal contents do not become formed in the colon but seep distally into the rectum. In the nonconstipated individual with a normal defecation reflex the rectum is not a reservoir of feces. For this reason mineral oil does not correct the altered physiology of constipation.

INDICATIONS FOR CIRCUMCISION

To the Editor—Can you give me information concerning the indications for circumcision? It was recently stated in a gathering of women that all enlisted men are circumcised by the Army unless already circumcised. I have observed that all male animals have the glans protected by the prepuce. Why remove it? Mabel D. Murphy M.D. Glendale 7 Calif.

ANSWER—The chief indications for circumcision are a prepuce that cannot be retracted over the glans, a few causes of which are phimosis, paraphimosis and persistent balanoposthitis. In many hospitals circumcision is done almost as a routine procedure. As a result perhaps many foreskins are needlessly sacrificed. On the other hand, this procedure prevents the occurrence of many penile disturbances. It is not true that all enlisted men in the armed forces are routinely circumcised.

STILLBIRTH AND PLACENTAL INFARCTS

To the Editor—A woman aged 28 after going through a normal pregnancy was delivered at term of a stillborn infant that was known to have died four days before delivery. The pathologist's diagnosis was (1) female stillborn in stage of autolysis and postmortem disintegration (2) multiple infarction of the placenta (3) Kline test on placental blood negative and no signs of syphilis present. The mother suffers obvious endocrine dysfunction and became pregnant with difficulty only after treatment with thyroid and synapoidin (a combination of chorionic gonadotropin and pituitary). What are the possible causes of this or any placental infarction? What are the probabilities of a repetition in succeeding pregnancies? What investigation might help to determine the cause of the placental abnormality? Lawrence H. Lief M.D. Jamesburg N.J.

ANSWER—Not much is known about the etiology of placental infarcts. Nearly every placenta shows infarct formation but the latter seldom produces any disturbances. However, when the infarct formation is extensive enough to involve a large part of the placental tissue there will result a deficient supply of blood to the fetus with interference in its development or death.

Clinically infarcts cannot be diagnosed, but large amounts of infarct formation are associated with nephritis and syphilis.

At present there is no known way of preventing the development of infarcts. Of course, when syphilis is present it should be treated. In cases of outspoken nephritis, pregnancy must usually be terminated in the interests of the mother, else in the latter part of pregnancy in most cases the baby is expelled prematurely and the placenta shows considerable areas of infarction.

This woman should have a thorough medical investigation, and if no disease is found she may safely become pregnant again. In a large proportion of stillbirths the cause cannot be found and most of these women subsequently give birth to healthy children. The thyroid and synapoidin almost certainly had no bearing on the fetal death, but were they really needed for the "obvious endocrine dysfunction"?

ASYMPTOMATIC NEUROSYPHILIS AND TREATMENT WITH TRYPARSAMIDE

To the Editor—A patient with late latent syphilis of eight years duration received treatment with neosarsphenamine and bismuth for the first two years. The blood and spinal fluid give a 4 plus Wassermann reaction. Organic or mental changes are not apparent. 1 Is it necessary to abstain from food and fluid for two to three hours prior to and subsequent to receiving an intravenous injection of tryparsamide? 2 In such a patient coming twice a week for treatment is bismuth or mapharsen the more effective to use in addition to the tryparsamide? 3 If tryparsamide is not tolerated what substitute is suggested? 4 How long should such patients be treated with tryparsamides and in general? 5 Is iodide orally advisable in such cases? 6 Is abstinence from food and fluids for two or three hours before and after injection of mapharsen recommended?

M. D. New York

ANSWER—A patient with syphilis of eight years' standing and a supposed positive spinal fluid cannot be regarded as having latent syphilis. A major distinction is to be drawn between patients with true latent syphilis (in whom by definition the spinal fluid should be normal) and those with asymptomatic neurosyphilis, in whom the prognosis is vastly more grave. Detailed suggestions for treatment cannot be provided without more details of the spinal fluid examination. It is assumed that there are no symptoms or neurologic evidence of involvement of the nervous system. The examination of the spinal fluid, however, should provide data concerning cell count, total protein content, quantitative Wassermann reaction and colloidal gold curve.

In general, fever therapy is more satisfactory for patients with neurosyphilis, asymptomatic or otherwise, than tryparsamide or any other arsenical drug whether pentavalent or trivalent.

If tryparsamide is employed, however, the following answers may be supplied to the specific questions asked:

1 No.
2 Tryparsamide should never be given twice a week. There is a serious risk of irremediable visual damage from its use once a week, and this risk is greatly increased if the interval between injections is lessened. If it is desired to use a bismuth compound in conjunction with tryparsamide, the two injections may be given the same day, obviating the necessity for twice weekly visits. Bismuth injections should be given to insure a concentration in the urine of 0.002 Gm or more of metallic bismuth per day. If, for a reason which does not appear in the query, it seems essential to treat the patient twice a week, mapharsen should be alternated with tryparsamide.

3 If the patient is unable to tolerate tryparsamide, a trial may be made of aldarone, another pentavalent drug which is said to be less prone to produce visual reactions than tryparsamide. Unfortunately, there are few satisfactory data concerning the effectiveness of aldarone.

4 This question cannot be answered without further and much more detailed knowledge of the situation.

5 No.
6 Yes.

THERAPY OF BONE LESIONS OF MYELOMA

To the Editor—The recent answer to a query on Therapy of Bone Lesions of Multiple Myeloma in *The Journal* Aug 5 1944 is in disagreement with both the bulk of the literature on the subject and with my experience based on the study of approximately thirty five histologically proved cases of multiple myeloma at the Massachusetts General Hospital during the past eleven years (Jacobson B. M. Krane F. Gall E. A. and Lingley, L. J. The Diagnosis of Multiple Myeloma to be published). Contrary to the answer cited roentgen therapy to areas shown to be involved rarely results in relief of pain. And with the exception of the extremely rare cases of solitary plasmoma the bone lesions of multiple myeloma are not radiosensitive and do not heal following roentgen therapy.

To the Editor—Is it possible for mineral oil to get through the intestine without some of it being emulsified and saponified? Can it escape some saponification in the intestinal and hepatic alkaline secretions? Would not such soap solution be an irritation and in time sclerose the mucous membrane?

M. D. Wyoming

ANSWER—Mineral oil (liquid petrolatum) cannot undergo saponification. Mineral oil is a mixture of hydrocarbons containing only hydrogen and carbon. Fats and fatty oils undergo saponification. Soaps are the alkaline salts of fats or fatty oils. Fats and fatty oils are glycerides or a combination of glycerol and fatty acids. Vegetable and animal oils are natural mixtures of various fats and fatty oils. Their resemblance to mineral oil is in their physical properties, such as consistency and unctuousness.

Mineral oil does undergo emulsification with the water of the gastrointestinal contents. This emulsification by its capacity for holding water and preventing its absorption from the colon and the dilution of the intestinal contents by the oil itself are the physical means by which mineral oil keeps the constipated stool soft.

The use of mineral oil as a laxative does have objections. It interferes with the absorption of fat soluble vitamins. In doses sufficient to make the feces mushy or liquid the intestinal contents do not become formed in the colon but seep distally into the rectum. In the nonconstipated individual with a normal defecation reflex the rectum is not a reservoir of feces. For this reason mineral oil does not correct the altered physiology of constipation.

INDICATIONS FOR CIRCUMCISION

To the Editor—Can you give me information concerning the indications for circumcision? It was recently stated in a gathering of women that all enlisted men are circumcised by the Army unless already circumcised. I have observed that all male animals have the glans protected by the prepuce. Why remove it? Mabel D. Murphy M.D. Glendale 7 Calif

ANSWER—The chief indications for circumcision are a prepuce that cannot be retracted over the glans, a few cases of which are phimosis, paraphimosis and persistent balanoposthitis. In many hospitals circumcision is done almost as a routine procedure. As a result perhaps many foreskins are needlessly sacrificed. On the other hand, this procedure prevents the occurrence of many penile disturbances. It is not true that all enlisted men in the armed forces are routinely circumcised.

STILLBIRTH AND PLACENTAL INFARCTS

To the Editor—A woman aged 28 after going through a normal pregnancy was delivered at term of a stillborn infant that was known to have died four days before delivery. The pathologist's diagnosis was (1) female stillborn in stage of autolysis and postmortem disintegration (2) multiple infarction of the placenta (3) Kline test on placental blood negative and no signs of syphilis present. The mother suffers obvious endocrine dysfunction and became pregnant with difficulty only after treatment with thyroid and synapoidin (a combination of chorionic gonadotropin and pituitary). What are the possible causes of this or any placental infarction? What are the probabilities of a repetition in succeeding pregnancies? What investigation might help to determine the cause of the placental abnormality? Lawrence H. Lief M.D. Jamesburg N. J.

ANSWER—Not much is known about the etiology of placental infarct. Nearly every placenta shows infarct formation, but the latter seldom produces any disturbances. However, when the infarct formation is extensive enough to involve a large part of the placental tissue there will result a deficient supply of blood to the fetus with interference in its development or death.

Clinically infarcts cannot be diagnosed, but large amounts of infarct formation are associated with nephritis and syphilis.

At present there is no known way of preventing the development of infarcts. Of course, when syphilis is present it should be treated. In cases of outspoken nephritis, pregnancy must usually be terminated in the interests of the mother, else in the latter part of pregnancy in most cases the baby is expelled prematurely and the placenta shows considerable areas of infarction.

This woman should have a thorough medical investigation, and if no disease is found she may safely become pregnant again. In a large proportion of stillbirths the cause cannot be found and most of these women subsequently give birth to healthy children. The thyroid and synapoidin almost certainly had no bearing on the fetal death, but were they really needed for the "obvious endocrine dysfunction"?

ASYMPTOMATIC NEUROSYPHILIS AND TREATMENT WITH TRYPARSAMIDE

To the Editor—A patient with late latent syphilis of eight years' duration received treatment with neosphenamine and bismuth for the first two years. The blood and spinal fluid give a 4 plus Wassermann reaction. Organic or mental changes are not apparent. 1 Is it necessary to abstain from food and fluid for two to three hours prior to and subsequent to receiving an intravenous injection of tryparsamide? 2 In such a patient coming twice a week for treatment is bismuth or mapharsen the more effective to use in addition to the tryparsamide? 3 If tryparsamide is not tolerated what substitute is suggested? 4 How long should such patients be treated with tryparsamides and in general? 5 Is iodide orally advisable in such cases? 6 Is abstinence from food and fluids for two or three hours before and after injection of mapharsen recommended?

M. D. New York

ANSWER—A patient with syphilis of eight years' standing and a supposed positive spinal fluid cannot be regarded as having latent syphilis. A major distinction is to be drawn between patients with true latent syphilis (in whom by definition the spinal fluid should be normal) and those with asymptomatic neurosyphilis, in whom the prognosis is vastly more grave. Detailed suggestions for treatment cannot be provided without more details of the spinal fluid examination. It is assumed that there are no symptoms or neurologic evidence of involvement of the nervous system. The examination of the spinal fluid, however, should provide data concerning cell count, total protein content, quantitative Wassermann reaction and colloidal gold curve.

In general, fever therapy is more satisfactory for patients with neurosyphilis, asymptomatic or otherwise, than tryparsamide or any other arsenical drug, whether pentavalent or trivalent.

If tryparsamide is employed, however, the following answers may be supplied to the specific questions asked:

1 No

2 Tryparsamide should never be given twice a week. There is a serious risk of irremediable visual damage from its use once a week, and this risk is greatly increased if the interval between injections is lessened. If it is desired to use a bismuth compound in conjunction with tryparsamide, the two injections may be given the same day, obviating the necessity for twice weekly visits. Bismuth injections should be given to insure a concentration in the urine of 0.002 Gm or more of metallic bismuth per day. If, for a reason which does not appear in the query, it seems essential to treat the patient twice a week mapharsen should be alternated with tryparsamide.

3 If the patient is unable to tolerate tryparsamide, a trial may be made of aldarson, another pentavalent drug which is said to be less prone to produce visual reactions than tryparsamide. Unfortunately, there are few satisfactory data concerning the effectiveness of aldarson.

4 This question cannot be answered without further and much more detailed knowledge of the situation.

5 No

6 Yes

THERAPY OF BONE LESIONS OF MYELOMA

To the Editor—The recent answer to a query on 'Therapy of Bone Lesions of Multiple Myeloma' in THE JOURNAL Aug 5, 1944, is in disagreement with both the bulk of the literature on the subject and with my experience, based on the study of approximately thirty-five histologically proved cases of multiple myeloma at the Massachusetts General Hospital during the past eleven years (Jacobson B. M., Krane F., Gall E. A. and Lingley, L. J. *The Diagnosis of Multiple Myeloma* to be published). Contrary to the answer cited roentgen therapy to areas shown to be involved rarely results in relief of pain. And with the exception of the extremely rare cases of solitary plasmoma the bone lesions of multiple myeloma are not radiosensitive and do not heal following roentgen therapy.

Bernard M. Jacobson Lieut. Comdr. (MC) U.S.N.R.

edema responded promptly and improvement began. The patient was discharged, afebrile, on the thirty-fourth hospital day.

One month after discharge he had regained his lost weight, but dizziness persisted.

The harmful effects of improperly given intravenous therapy are well illustrated by this case. In spite of careful nursing and attention to diet with moderate

Chart 1—Effect of intravenous fluids in case 1, man aged 45, rash present four days

amounts of fluid by mouth the patient became more toxic. Since he had been sweating profusely, losing water and salt, prerenal azotemia and hypochloridemia developed. These conditions readily responded to intravenous saline and glucose solution, but although the nonprotein nitrogen and chlorides returned to normal the patient clinically was worse. Increasing edema, rales in the lungs and pneumonia developed. The edema was then recognized as being partially due to hypoproteinemia. With the administration of blood and plasma the edema disappeared from the lungs and subcutaneous tissues, and the patient rapidly recovered. Saline solution and glucose were given with impunity after adequate administration of blood and plasma.

The failure of quinine, sulfadiazine and intravenous metaphen as specifics is illustrated. A clinical recrudescence occurred simultaneously with the initiation of quinine therapy.

Chart 2—Effect of parenteral fluids in case 2, girl aged 2 years, weight 11.7 Kg, rash present six days

The experience with this adult was duplicated in the case of a child.

CASE 2—A tick was removed from behind the ear of a 2 year old white girl two weeks before entry. Headache and high fever developed six days later. A rash appeared on the extremities at the same time and then became generalized.

On admission the child was stuporous and dehydrated with a temperature of 40 C (104 F), a pulse rate of 106 and 60 respirations per minute. A generalized petechial macular rash

was present, and there were purpuric areas on the toes, heels and elbows. Gallop cardiac rhythm with a soft apical systolic murmur was noted, but there was no peripheral venous engorgement. The lungs were clear. The spleen extended 4 cm below the costal margin. Occasional muscular twitchings and generalized clonic convulsive movements occurred.

The accessory clinical findings are summarized in table 2 and chart 2. The urine contained many hyaline and granular casts. The spinal fluid was negative. The agglutination for Proteus OX₁₀ rose to 1:320. When the serum proteins were 3.4 Gm per hundred cubic centimeters, the albumin fraction was 1.7 Gm per hundred cubic centimeters, calcium 9 mg per hundred cubic centimeters and phosphorus 2.9 mg per hundred cubic centimeters.

During the patient's first week in the hospital the temperature fluctuated between 37.2 and 40.5 C (99 and 105 F), with a disproportionately high, feeble pulse and rapid or Cheyne Stokes respirations. During the first ten days 1,720 cc of whole blood, 1,050 cc of plasma and 2,400 cc of other fluids (chart 2) were given intravenously or by bone marrow. In five days of treatment the blood chemical findings returned almost to normal. Following the restoration of plasma protein the generalized edema, which had been increasing, disappeared. With the restoration of chloride the convulsive seizures ceased. The patient received, parenterally, ascorbic acid and vitamin B complex during the third week; nutrition was maintained by gavage feeding. By the tenth hospital day the temperature averaged 38.7 C (102 F), the pulse 136 and respirations 30

Chart 3—Effect of intravenous fluids in case 3, boy aged 15 years, rash present eight days. The discrepancy between the values for total serum proteins as determined by the Kjeldahl method and calculated from values of plasma specific gravity is unexplained.

to 40. The child became afebrile by the fifty-seventh hospital day. Pronounced neurologic changes persisted after clinical recovery: generalized spasticity, mental confusion, choreoathetoid movements of the extremities, hyperactive reflexes and a bilaterally positive Babinski sign were still present at discharge two and a half months after onset.

The anemia and albuminuria present on admission are evidence of the severity of the infection. The severity and persistence of damage to the central nervous system noted in this case occur occasionally in Rocky Mountain spotted fever. Because the patient was comatose, a gavage tube was inserted; the inadequacy of oral fluid and mineral replacement therapy alone is illustrated by the table. Subcutaneously administered parenteral fluids were not absorbed rapidly enough to supplement adequately oral therapy. Pre-renal azotemia, edema and hypoproteinemia developed; the loss of protein in the urine contributed to the hypoproteinemia. A dramatic diuresis occurred simultaneously with the initiation of protein replacement therapy given by bone marrow. The tremendous amount of blood and plasma given this 2 year old child

illustrates the safety of properly chosen intravenous therapy. One transfusion of blood from a donor convalescent from the disease was given without reaction.

CASE 3—A boy aged 15 years complained of a painful post-auricular nodule, headache, generalized muscular aching and a sore throat. A rash developed eight days before admission to the hospital. Three days later he had a shaking chill followed by high fever and stupor. No definite history of tick bite was obtained.

day and showed 8 mononuclear cells a strongly positive Pandey reaction and a negative benzidine test. The agglutination with Proteus OX₁₀ became positive in a dilution of 1:640 and the complement fixation test for Rocky Mountain spotted fever was positive in a dilution of 1:32. The van den Bergh test ranged from 20 to 11 mg per hundred cubic centimeters. Hippuric acid excretion tests during the first eleven days showed 0.22 Gm of benzoic acid excreted, by discharge this had increased to 3.00 Gm. Urea clearance tests were at the lower level of the normal range. The nitrogen output in the urine for a period

On admission the patient was comatose his temperature was 38.9 C (102.5 F), pulse 104 respirations 28 and blood pressure 80/58. A generalized reddish purple macular rash was present. The eye grounds showed papilledema. The neck was stiff and painful on motion. The lungs were clear. The spleen was palpable. The liver was not felt. Minimal nonpitting edema of the feet was noted. Sustained ankle clonus was present bilaterally.

The accessory chemical findings are summarized in table 3 and chart 3. On admission with serum proteins of 4.8 Gm per hundred cubic centimeters, the albumin was 2.1 Gm per hundred cubic centimeters. At the time of discharge the albumin globulin ratio was 1.0. The spinal fluid which was clear on admission became xanthochromic by the third hospital

of seventy-eight hours was determined. The data indicated the conversion of nearly all the nitrogen to urea. The amount of nitrogen eliminated by the kidney was equivalent to the destruction of 561 Gm of dry protein or 7 pounds of skeletal muscle in seventy-eight hours.

The temperature ranged to 40.4 C (105 F), with a corresponding pulse rate until the twelfth hospital day it remained around 38 C (100-101 F) for ten days longer. With massive intravenous therapy the blood pressure rose to 120/70 but gradually dropped back to 100/60 where it became stabilized. The patient had received 50 cc of hyperimmune rabbit serum by the fifth hospital day (thirteenth day after the appearance of the rash) without striking change in the degree of toxicity. After the initial dehydration was overcome by intravenous and

subcutaneous infusions, adequate fluids were given by constant duodenal intubation. A high protein, high calory liquid diet, with additional sodium chloride and vitamins was given by gavage tube. As much as 1,500 cc of plasma was given intravenously in nine hours. Lumbar punctures relieved the stupor and periodic apnea. The sensorium cleared gradually, but at the time of discharge the neurologic signs had not entirely disappeared.

This case illustrates the life saving property of large doses of plasma in the peripheral circulatory collapse that frequently accompanies severe infections. The great protein requirement is shown by the studies on nitrogen metabolism. No impairment of kidney excretory function was demonstrated. The protein was given ready made, since the liver function studies indicated impairment. The severity of the encephalitis is illustrated by the need for gavage tube feeding, catheterization and lumbar punctures to reduce the cerebrospinal fluid pressure, as well as by the stupor and partial

"myocardial intoxication" or "renal intoxication," although little evidence has been found post mortem to support this theory. The kidneys are not seriously damaged, as is shown by the urea clearance studies in case 3 and by the ready reduction in blood nonprotein nitrogen when adequate fluids are properly given. Some of the edema, especially that occurring later in the course of the disease, is due to lowering of the plasma proteins.

The disease is not usually diagnosed until after the endothelium and smooth muscle of blood vessels have been damaged, so that the familiar skin eruption results. The injury to blood vessels produces physiologic changes analogous to those caused by burns. Plasma, water and crystalloids leak out of the damaged vessels, producing hemoconcentration and circulatory failure. The tissues of the patient may not be dehydrated, and large volumes of water and crystalloids given by mouth or parenterally may aggravate the situation. With the leakage of fluid

muscular paralysis. Once deficiencies in water and salt were made up by parenteral administration of fluids, an adequate intake was maintained by duodenal intubation even though the patient was comatose.

This was the first case treated in this hospital with specific hyperimmune rabbit serum, little beneficial effect was noted from this, since the disease was well advanced before the patient was admitted.

COMMENT

Intravenous supportive therapy properly given is not harmful in Rocky Mountain spotted fever but may be life saving. The confusion over this point in the literature has arisen because of failure to appreciate the pathologic physiology of the disease.

Mechanism of the Edema—Early in the course of the disease a moderate amount of generalized edema involving the face, eyes, hands and legs frequently develops. It is firm in consistency and does not tend to localize in the dependent portions of the body. It is not accompanied by orthopnea. The edema cannot be attributed to cardiac failure, for venous engorgement, rales in the chest and other evidences of cardiac failure are not present. The fatalities are said to result from

forced out by the arterial pressure, the protein content of the blood is lowered so that its osmotic pressure on the venous side of the capillary bed is reduced and its ability to hold water in the vascular bed or to draw back fluid from the tissues is lost.

The development of edema is further aggravated by deficient formation of blood protein. Delirium and general intoxication result in a reduced intake of food necessary for the formation of new protein. Because of liver damage, which is a recognized part of the pathology of the disease, protein is not synthesized even though adequate nutrition is maintained. The pronounced reduction of liver function is demonstrated by the hippuric acid studies and by the slightly elevated van den Bergh reaction and icterus index. The extent of this impairment and its significance in relation to therapy has not been sufficiently appreciated. The very large amount of protein metabolized daily is indicated by the nitrogen excretion studies done in case 3. In patients who are stuporous or delirious, tube feeding may be necessary. A high protein, high carbohydrate diet supplemented by casein, if necessary, should be given to protect the liver and to assist in the regeneration of plasma proteins. If liver damage is very severe, ready

made protein in the form of blood or plasma should be given intravenously

Harmful Effects of Intravenous Fluids—In Rocky Mountain spotted fever one of the most severe forms of peripheral circulatory collapse or "medical shock" develops. The "toxic" condition is strikingly similar to early "shock" associated with functional capillary damage from any cause, experimentally this may be produced by burns, bacterial toxins or other substances. Because of this alteration in the normal physiology of the body it is easy to understand why improperly chosen intravenous fluids would be ineffective and might even be harmful. Since the osmotic pressure of the blood is not maintained, intravenous glucose or saline solution would rapidly leave the blood stream and might even tend to wash more protein out into the tissues. This possibility has been discussed in detail by Minot and Dodd⁵ and by Beard and Blalock⁶. The mistaken conception that no intravenous fluids should be used has become entrenched so firmly that even the packages of antiserum contain the admonition "Not to be used intravenously."

The Beneficial Effects of Plasma—It has been shown by many workers that if "shock" is treated early enough the changes are reversible. Since patients with Rocky Mountain spotted fever present the picture of peripheral circulatory collapse, plasma and whole blood would be the fluids of choice. If the hemoglobin or hematocrit determinations indicate a loss in red cells, whole blood would be preferred until this condition is remedied. We have not observed the severe reactions to transfusions reported by others⁴. Blood or plasma obtained from a convalescent donor seems to have no advantage over that obtained at random. A large quantity of blood or plasma may be required in a short time as is evidenced by cases 2 and 3. Once the peripheral circulatory collapse and hypoproteinemia are controlled, the proper selection of additional parenterally administered fluids will depend on the hematocrit, blood count and blood chemical studies.

It is conceivable that, in extreme degrees of vascular damage, plasma transfusions may be useless, the plasma passing into the tissues or peritoneal cavity, producing only a transient decrease in the hematocrit and no improvement in peripheral circulation or protein level. It is also conceivable that an overdose of plasma may be given in instances of severe damage. The fluid may not be lost from the body but remain in the tissues and eventually return to the circulation through the lymphatics. The resulting increase in blood volume, as the capillaries recover, might be harmful.

The Proper Use of Crystalloids—As a result of profuse continued sweating, the blood chlorides may be moderately lowered, muscular tenderness, twitching, fibrillation and convulsions are found, as in heat cramps, and disappear with the restoration of chlorides. Simultaneously prerenal azotemia may occur, this also is common in sublethal shock. In those patients who are treated before the circulatory failure becomes irreversible, no permanent impairment of kidney function results. Crystalloids alone are usually adequate to correct this condition. The solution may be isotonic

or hypertonic saline with or without glucose isotonic solution of three chlorides, calcium chloride sodium lactate or whatever is necessary. The use of all fluids should be based on the laboratory data and the clinical condition of the patient⁸. In general the amounts given should be sufficient to restore the circulating blood volume and the blood constituents to normal. Because of the abnormal permeability of the capillaries and the resultant loss of fluids from the vascular tree repeated laboratory determinations should be made to be sure that the desired result has been obtained. If properly chosen and administered intravenous therapy is safe and may prove life saving.

Other Methods of Treatment—Eradication of the infection is made difficult because of the underlying pathology of the disease. The rickettsias are located intranuclearly, hence any therapeutic agent must pass through two cell membranes to reach the organism. It is probably for this reason that the serum recently introduced by Topping⁹ has been found to be effective only in the first three days of the rash before a sufficient number of parasites have become established in cells. No specific chemotherapeutic agent is yet available. Quinine and intravenous neoarsphenamine dissolved in a 1:1,000 solution of aqueous metaphen have been used⁹. The sulfonamides have been ineffective and occasionally appear to make the patient worse⁴. Experimentally guinea pigs treated with sulfonamides died sooner than those which were not treated¹⁰. Penicillin has not been reported to be helpful.

The liver may be aided in the regeneration of plasma proteins by the intravenous administration of amino acids. The oral vitamin intake can be supplemented by the addition of inosin, ascorbic acid and thiamine hydrochloride to the intravenous injections. The requirement for these substances is increased many times in infections. Thiamine may help prevent shock and hence be especially helpful,¹¹ ascorbic acid may assist in maintaining the continuity of vascular endothelium.

Treatment of Complications—Pneumonia is a frequent complication. With the lowering of the blood osmotic pressure pulmonary congestion develops. The protein-containing edema fluid supplies a perfect culture medium for any pathologic organism which may be present in the upper respiratory tract. If the infecting organism does not respond to the sulfonamides or if these are felt to be contraindicated, x-ray therapy may safely be given,¹² as was done in case 1. Penicillin may be useful in such an instance, but we have not yet had an opportunity to try it.

Thrombophlebitis may result from damage to the endothelium of larger blood vessels. The reduction of circulating blood volume, the tendency toward peripheral circulatory failure and the stasis occurring in the presence of vascular damage favor the development of thrombosis. When this occurs in the leg, injection of procaine hydrochloride around the lumbar sympathetic

ganglions may reduce the pain and prevent the aggravation of restlessness

For the severe headache, which may be accompanied by actual blurring of the optic disk because of cerebral edema, lumbar puncture to reduce the cerebrospinal fluid pressure may be helpful. Occasionally the changes in the blood supply to the brain may result in temporary mental or neurologic changes which disappear slowly over a period of months, as in case 1, or in more permanent damage to the brain, as in case 2.

Ileus, probably due to irritation of the central nervous system resulting from vascular injury, may prove extremely resistant to therapy, as in case 1. Heavy sedation with barbiturates, scopolamine or other drugs may be necessary. Occasionally as a result of damage to the central nervous system the patient may sleep with his eyes open and develop corneal ulcers. Instillations of some mild substance such as cod liver oil will prevent drying out of the cornea. *Herpes simplex* may be troublesome but rarely is dangerous. Because of the damage to the blood vessels and the resultant tendency toward anoxia and gangrene, constant and painstaking care must be given to the skin to prevent the development of decubitus ulcers.

SUMMARY

Rickettsial spotted fever is a severe systemic disease. It is rarely diagnosed until the skin rash has appeared. No specific therapeutic agent is available which is effective after the third day of the rash, hence therapy must be largely supportive.

Regulation of supportive therapy, based on the pathologic physiology of the disease, has not been attempted. Because of the vascular lesions, the loss of circulating body fluids, particularly protein, is analogous to that in burns, and peripheral circulatory collapse may develop if inadequate or improper treatment is given. The administration of saline solution or glucose without blood or plasma will aggravate rather than correct the abnormal physiology by washing out further protein.

Intravenous therapy, properly chosen, is not harmful, as it has been reported to be, but may prove life saving. It should include plasma and whole blood in adequate quantities in addition to glucose, salts, vitamins and amino acids. Careful laboratory control in choosing the type and quantity of parenteral or oral fluids to be administered is important.

The elevation of the blood nonprotein nitrogen and lowering of blood chlorides are connectable.

Edema of the subcutaneous tissues and lungs can be produced by excessive administration of crystalloids. The increase in water binding power of the circulating fluid produced by the administration of blood and plasma, pulls water out of the interstitial spaces and reduces the edema. The peripheral circulation can be supported and the blood pressure raised from shock levels.

The serum proteins are reduced, nitrogen excretion studies suggest that protein destruction is great. The impairment of liver function makes protein replacement therapy necessary for variable lengths of time.¹³

THE PREOPERATIVE PATENT DUCTUS

M. J. SHAPIRO

Clinical Director, Minneapolis Children's Hospital
MINNEAPOLIS

Since it is now possible to correct patent ductus arteriosus by surgery it is of interest to determine how the correct diagnosis be made, to avoid unnecessarily to a major surgery. Those with this lesion the possibility of surgery. Since the first successful ligation by Gross in 1938 patients have been referred for surgical treatment, who on examination have other types of congenital heart disease. Not all patients with patent ductus arteriosus have been diagnosed before the age of school age. In most instances were referred to the heart clinic because of a murmur found during the school physical examination. Often the parents have been told by their pediatricians or pediatricians that the child "would grow out of it." It is for these reasons that the diagnosis of patent ductus arteriosus is both timely and important.

In utero at term, the ductus arteriosus is of considerable size which acts as a by-pass of blood away from the fetal lungs and carries blood from the pulmonary artery to the aorta. In the newborn infant the ductus closes within a few days after the first breath is taken. Recent studies suggest that failure of closure in uncomplicated patent ductus arteriosus may result from lack of constriction of the blood, possibly because of obstruction of the anastomoses in the newborn infant.

Two types of patency of the ductus may occur. The duct may remain open as part of a serious developmental defect and may act as the only means of maintaining circulation in a heart seriously impaired by congenital defects. Such patients have unmistakable evidence of congenital heart disease. In the type of case which is curable by surgery the patent ductus is the only defect present. The heart is otherwise normally developed. Strictly speaking the uncomplicated isolated patency of the ductus is not a congenital lesion, as it occurs after birth and has nothing to do with developmental defects of the heart.

SEX AND AGE INCIDENCE

We have had under observation at the clinic for a variable number of years 62 patients in whom a definite diagnosis of uncomplicated patent ductus arteriosus could be made. Of these 62 patients 47 were females and 15 were males (table 2). In all series of cases reported this same preponderance of females is present. This is more than an accidental finding, but there seems to be no clearcut explanation for this sex preponderance.

When our patients were last examined 18 of them were up to 10 years of age, 27 were between 10 and 20 years of age, 10 between 20 and 30, 4 between

Read before the Section on Pediatrics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

13. After this paper was written a similar study in cases of epidemic typhus was reported. Woodward, T. E. and Bland, E. F. Clinical Observations in Typhus Fever with Special Reference to the Cardiovascular System. *J. A. M. A.* 126: 287-293 (Sept. 30) 1944.

30 and 40, 1 between 40 and 50 and 2 between 50 and 60 years of age. The 3 patients over the age of 40 have since died. A study of the literature indicates that while patients over the age of 40 with patent ductus arteriosus are occasionally seen, it is true that such patients rarely live beyond this age. As previous studies have revealed,² most of them die either of subacute bacterial endarteritis or of congestive heart failure in early adulthood.

Thirty-five of our patients have been observed up to five years, 15 between 5 and 10 years and 12 between 10 and 20 years.

CLINICAL CHARACTERISTICS

Stunting of growth has been considered a typical finding in patients with patent ductus arteriosus. The retardation of growth results from the shunting of blood from the periphery to the pulmonary circulation. However, in my experience stunting of growth is not always found. Some of the more serious cases with definite evidence of cardiac strain have shown no abnormality of growth. Thirty-three of the patients (table 3) have been normally developed, 23 were undersized and 6 were obese.

On physical examination the most characteristic finding in this lesion is the so-called machinery murmur, which is heard over the first or second interspace just to the left of the sternum. The murmur is pathognomonic and, once heard, is easily recognized. The murmur is continuous throughout the heart cycle, and

TABLE 1—*Electrocardiographic Observations*

Normal	52
Left axis deviation (slight)	5
Right axis deviation (slight)	1
Other changes	4

within the murmur an accentuated pulmonic second sound is usually heard. The murmur leads up to the accentuated second sound and then fades away during diastole.

With our present knowledge it is my feeling that a diagnosis of patent ductus arteriosus should not be made unless this characteristic murmur is present. A study of the older literature will reveal the statement that patent ductus arteriosus can occur in patients in whom only a systolic murmur is heard. In my experience all of our patients who have been studied either at the operating table or at postmortem and in whom the diagnosis has been verified have had this characteristic murmur with 1 exception, and in this case no murmur at all was heard. In our series 61 patients had this murmur, while in 1 instance already mentioned in a patient 46 years of age in whom a very large open ductus was found at postmortem no murmur was found.

A thrill, palpable over the point of maximum intensity of the murmur, is usually present. Fifty-three of our patients had this thrill. In 9 instances no thrill was palpable.

The peripheral vascular findings will vary in accordance with the size of the ductus. In patients in whom the ductus is small the pulse pressure may be normal, however, in those individuals in whom there is any

considerable leak through the open ductus the peripheral vascular findings will be much the same as those found in aortic regurgitation: increased pulse pressure, pistol-shot femorals, capillary pulse and the like. In 14 of our patients the pulse pressure was found normal and

in 48 there was a definite increase in pulse pressure, in these the accompanying characteristic peripheral vascular findings were noted.

ELECTROCARDIOGRAPHIC FINDINGS

The electrocardiogram in patent ductus arteriosus is important from a negative point of view. In the uncomplicated lesion the electrocardiogram is within normal limits. Occasionally one finds a slight right or slight left axis deviation, and there may also be present slight slurring in one or two leads. However, if a pronounced right axis deviation is found the diagnosis of an uncomplicated patent ductus arteriosus should be seriously questioned. This is also essentially true when a pronounced left axis deviation is found. In our series 52 patients had normal findings (table 1), 5 had a slight left axis deviation, 1 had slight right axis deviation, and 4 had other slight changes.

X-RAY FINDINGS

Roentgen studies are of great value, not only in making the diagnosis, but also in observing the progress of the individual case. Much can be learned in regard to the severity of the leak and the amount of cardiac strain present by x-ray observation. In patients with small ducts the heart may be within normal limits,

THE PREOPERATIVE DIAGNOSIS OF PATENT DUCTUS ARTERIOSUS

M. J. SHAPIRO, MD

Clinical Director, Minneapolis Children's Heart Clinic and Hospital
MINNEAPOLIS

Since it is now possible to cure a patent ductus arteriosus by surgery it is of utmost importance that the correct diagnosis be made, lest we subject patients unnecessarily to a major surgical procedure or deny those with this lesion the possibility of surgical cure. Since the first successful ligation of a patent ductus by Gross in 1938 patients have been referred to me for surgical treatment, who, on examination, were found to have other types of congenital heart lesions but did not have patent ductus arteriosus. By far the great majority of patients who have come under my observation have not been diagnosed correctly until they were of school age. In most instances these patients were referred to the heart clinic because a murmur was found during the school physical examination. Too often the parents have been told by their family physicians or pediatricians that the child "would outgrow the condition." It is for these reasons that a discussion of the various aspects of the diagnosis of patent ductus arteriosus is both timely and important.

In utero at term, the ductus arteriosus is a vessel of considerable size which acts as a by-pass directing the blood away from the fetal lungs and carrying blood from the pulmonary artery to the aorta. In the normal newborn infant the ductus closes within a few minutes after the first breath is taken. Recent studies¹ suggest that failure of closure in uncomplicated cases of patent ductus arteriosus may result from lack of oxygenation of the blood, possibly because of obstruction of the air passages in the newborn infant.

Two types of patency of the ductus may occur. The duct may remain open as part of a serious developmental defect and may act as the only means of carrying on circulation in a heart seriously impaired by congenital defects. Such patients have unmistakable evidence of congenital heart disease. In the type of case which is curable by surgery the patent ductus is the only defect present. The heart is otherwise normally developed. Strictly speaking the uncomplicated isolated patency of the ductus is not a congenital lesion, as it occurs after birth and has nothing to do with developmental defects of the heart.

SEX AND AGE INCIDENCE

We have had under observation at the clinic for a variable number of years 62 patients in whom a definite diagnosis of uncomplicated patent ductus arteriosus could be made. Of these 62 patients 47 were females and 15 were males (table 2). In all series of cases reported this same preponderance of females is present. This is more than an accidental finding, but there seems to be no clearcut explanation for this sex preponderance.

When our patients were last examined 18 of them were up to 10 years of age, 27 were between 10 and 20 years of age, 10 between 20 and 30, 4 between

RAY FINDINGS

Roentgen studies are of great value, not only in making the diagnosis, but also in observing the progress of the individual case. Much can be learned in regard to the severity of the leak and the amount of cardiac strain present by x-ray observation. In patients with small ducts the heart may be within normal limits

2. Shapiro M. J. and Keys Ancel. The Prognosis of Untreated Patent Ductus Arteriosus and the Results of Surgical Intervention. Am J M Sc 206: 174-183 (Aug) 1947.

to size. There is almost always a slight enlargement of the pulmonary trunk. The enlargement of the pulmonary trunk may be apparent only on fluoroscopy or by obtaining films in oblique views. In patients with larger ducts and in whom there is considerable leak from the aorta into the pulmonary artery there will be found enlargement of both left and right ventricles as well as moderate to pronounced enlargement of the pulmonary trunk. The branches of the pulmonary artery in the lungs will also be enlarged. On fluoroscopy these pulmonary branches will be seen to pulsate.

In 22 of our patients (table 4) no enlargement of the heart was discovered, 21 had slight enlargement, 15 had moderate enlargement and 4 had pronounced enlargement of the heart. In 10 instances no evidence of enlargement of the pulmonary artery could be made out, 36 had slight enlargement, 15 moderate and 1 pronounced. In 36 instances there was no enlargement of the pulmonary branches, 13 slight, 12 moderate, and 1 pronounced.

By postmortem (3 operative)	7	0

DIAGNOSTIC VERIFICATION

We have had the opportunity of checking our diagnosis in 23 instances (table 5). In 19 patients who have been operated on a patent ductus was found in each instance. Three of these patients died and were further studied post mortem. In the 4 patients who died of this lesion not operated on and were studied post mortem, the diagnosis was correct in each instance, so that up to the present writing no errors in diagnosis have been made in our clinic.

DIFFERENTIAL DIAGNOSIS

There are several cardiac conditions which may be confused with patent ductus arteriosus. One of the most important, especially in infants and young children, is the so-called venous hum. This is also a continuous murmur heard over the base of the heart. It is usually not as loud as the characteristic machinery murmur. The venous hum is generated in the vessels of the neck, may be heard over the base of the heart and not infrequently is heard as far down as the apex. The murmur can be obliterated by moving the child's head from side to side or by applying pressure with the finger on the neck vessels. Of course none of the other findings of patent ductus arteriosus will be present.

Occasionally the diastolic murmur of aortic regurgitation will simulate the machinery murmur. In aortic

regurgitation, however, there is invariably a pause between the systolic and diastolic murmurs. These murmurs are usually heard lower down along the left border of the sternum. The blood pressure findings may be exactly the same as in patent ductus arteriosus. X-ray studies, however, will reveal no enlargement of the pulmonary trunk or vessels in the lungs. The enlargement of the heart in aortic regurgitation will, of course, involve primarily the left ventricle, producing a contour which is distinctly different from that found in patent ductus arteriosus. The electrocardiograph in well developed aortic regurgitation will reveal a pronounced left axis deviation.

Patients with interauricular septal defect commonly exhibit X-ray changes which simulate the findings in patent ductus arteriosus. On fluoroscopy the contour of the heart may suggest that found in patent ductus arteriosus, however, in most instances the heart is considerably larger and more rounded in patients with interauricular septal defects. The pulmonary vessels are also usually much larger and pulsate much more in the septal defect. The leak in auricular defect is intracardiac in contrast to that in patent ductus. The peripheral vascular findings in interauricular septal defect are normal, in contrast to the characteristic findings in patent ductus arteriosus. There should be no difficulty in making a differential diagnosis between these two lesions.

In patients with large defects of the interventricular septum, the shunt from left to right may be sufficient to produce enlargement of the pulmonary artery and its branches. The contour of the heart may simulate that in patent ductus arteriosus. In the ventricular septal defect the murmur is not of the machinery type, is heard best at the lower end of the sternum and is not accompanied by the characteristic peripheral vascular findings. The systolic murmur heard over the second left interspace in such instances is produced by the enlarged pulmonary artery and has none of the characteristics of the machinery murmur. Various other types of congenital heart lesions are commonly accompanied by enlargement of the pulmonary artery. Such localized increase in size of the pulmonary trunk in itself is not enough to make a diagnosis of a patent ductus.

DIAGNOSTIC CRITERIA

The diagnostic criteria of patent ductus arteriosus may be summarized as follows:

- 1 Machinery murmur
- 2 Thrill in pulmonary area
- 3 Enlarged pulmonary artery
- 4 Enlarged and pulsating pulmonary vessels
- 5 Enlarged heart
- 6 Increased pulse pressure
- 7 Stunting of growth
- 8 Absence of cyanosis and clubbing of fingers
- 9 Normal electrocardiogram
- 10 History of heart disease from early childhood

CONCLUSIONS

- 1 The diagnosis of patent ductus arteriosus can be made without error.
- 2 Patients should not be referred for surgical treatment unless they show the characteristic machinery

murmur The only exception to the rule is the occasional patient with a large patent ductus who may exhibit no murmurs

3 Patients with cyanosis and clubbing of the fingers do not have uncomplicated patent ductus They cannot be treated surgically

4 Pronounced electrocardiographic changes are not part of the picture of simple patent ductus arteriosus

ABSTRACT OF DISCUSSION

DR HARRY VESELL, New York In reference to the murmur in patent ductus arteriosus, in the past several years it has been the general opinion of those who have reported on this subject that the continuous murmur is essential to the diagnosis I have seen 3 cases in which only the systolic murmur was present These cases presented the other clinical and x-ray evidence of patent ductus arteriosus In 1 of them in addition there was subacute bacterial endocarditis, and operation revealed a wide ductus arteriosus but a short one, almost just a fistula A test I have found of some use in helping to confirm the diagnosis is the one described by Bohn It is the determination of the blood pressure immediately after exercise With the blood pressure cuff on the arm, Bohn has a patient do fifteen squats, and within one minute after the end of this exercise he has noted the systolic pressure go up slightly, but the sign he considered pathognomonic is the lowering of the diastolic pressure, which I have seen go down from 60 to 30 or 20 I have found the sign not positive in 1 case in which there was a patent interauricular septum, the diagnosis being proved by angiocardiology The test has also been confirmed by Lewicki The first case of subacute bacterial endocarditis on a patent ductus with recovery following operation was reported by Dr Turoff and myself in 1940 Recent follow-up of these earliest cases reveals that recovery has occurred and four and one half years after the operation the patients are working

DR M J SHAPIRO, Minneapolis I have not seen a proved case of suspected patent ductus arteriosus with only a systolic murmur I shall still insist on the presence of the typical machinery murmur before a definite diagnosis is made This is particularly true if surgical treatment is being considered The results of surgery have not all been good The mere making of a correct diagnosis of patent ductus arteriosus is not enough indication for surgical intervention Two of our patients who were operated on developed subacute bacterial endarteritis after surgery One of them died and the other one has been treated with penicillin and apparently has recovered from his blood stream infection Until we have accurate statistical data on the effects of surgery, it would be wise to operate on only those patients who show some evidence of cardiac strain or stunting of growth It is conceivable that in the near future, with the perfection of this surgical procedure, all patients with patent ductus arteriosus might be subjected to surgery, even as a prophylactic measure

Improvements in Obstetrics During the Eighteenth Century—With the publication of Mauriceau's text on obstetrics in 1668, this branch of medicine was well on the way to a specialty Physicians rather than midwives assumed the leading role and the various medical schools established departments in obstetrics France, still a leader in the field, produced several able midwives, among whom were Angelique Marguerite Boursier de Coudray and Marie Louise Lachapelle At the beginning of the century several outstanding obstetricians, who had made a mark in the last decades of the preceding century were still active—G Mauquest de la Motte (1655-1737) Hendrik van Deventer (1651-1724), Johann van Hoorn (1661-1721) and Jean Palfyn (1650-1730)—Ricci, James C The Gynecology Gynaecology, Philadelphia, Blakiston Company 1943

RECENT TRENDS OF LEPROSY IN THE UNITED STATES

REPORT OF SEVEN HUNDRED CASES AT THE NATIONAL LEPROSARIUM

RALPH HOPKINS, MD

Consulting Dermatologist United States Marine Hospital Carville La,
and Emeritus Professor of Diseases of the Skin Tulane University
of Louisiana School of Medicine

NEW ORLEANS

AND

G H FAGET MD

Medical Officer in Charge United States Marine Hospital
CARVILLE, LA

In June 1928 a report was read to the Section on Dermatology and Syphilology of the American Medical Association by Dr Oswald E Denney, then officer in charge of the National Leprosarium¹ In that statistical report special reference was made to the epidemiology of leprosy in the United States, and the

Yearly admissions of new cases and average daily population for fifty years

trend of the disease in other respects was noted After a decade and a half this supplemental report is made to show in what respects the present trends are in conformity with those reported fifteen years ago and what new developments have occurred

INCIDENCE

The number of patients admitted to the National Leprosarium from July 1928 to January 1944 has been 723 This number can by no means be taken as an exact index of the total number of individuals afflicted with leprosy in the United States, nor does the number admitted from any particular geographic area indicate accurately the comparative prevalence of leprosy in that area However, the large number of cases admitted continuously over long periods of time from some localities do show in a general way a trend toward

Authority given for publication by the Surgeon General of the U S Public Health Service Washington D C

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL The complete article appears in the authors reprints 1 Hopkins R and Denney O E Leprosy in the United States A Statistical Study of Seven Hundred Cases in the National Leprosarium J A M A 92 191 (Jan 19) 1929

is significant, as during that time many opportunities for spreading the infection, especially in the home, can be presumed to have existed

RACE

Of the inmates of the Leprosarium 577 were of the white race, 66 were Negroes, 40 were Filipinos, 10 were Hawaiians and 30 were of the yellow race

A comparison in native born Louisianians of the incidence in the Negro and the white races shows that there were 34 Negroes and 142 white persons admitted to the Leprosarium during the fifteen year period. The total population of Louisiana in 1940 was 2,363,880. The Negro population amounted to 849,303 and the white to 1,484,467.

The percentage of Negroes in the entire Louisiana population, therefore, was 37.1. The percentage of Negroes admitted to the Leprosarium from Louisiana was 19.3. It seems from these figures that there are approximately half as many Negroes with leprosy in the state in comparison with white persons as might be expected from the ratio of the races to each other in the entire population.

	723	100.0	100.0

SEX

In the report made in 1928 there were 72.3 per cent males and 27.7 per cent females admitted to the Leprosarium. This percentage is approximately the same as that from almost all countries in which leprosy has been reported, and the incidence in males and females admitted to the National Leprosarium since 1928 is in nearly the same ratio, there were 499 males and 224 females admitted during the last fifteen years, a proportion again of more than two males to one female.

At variance with the almost universal rule of two male leprosy patients to one female patient is the exception found among the native born Negroes, of whom there were admitted 25 men and 27 women. Native born admissions of all races other than Negro showed 246 males and 122 females.

No satisfactory explanation is offered for the almost universal preponderance of males over females nor for the exception found in regard to the Negro race. A correct explanation perhaps would add important knowledge concerning the epidemiology of leprosy. The number of our cases is so small that conclusions should not be drawn from them, but similar findings of an equal incidence in the sexes have been reported by Saunders and Guinto⁶ in the

exceptions cited to the rule of incidence in the different sexes have all occurred either in foreign countries with predominating Negro populations or in the United States in the Negro race.

TYPES OF LEPROSY

For the purpose of this report, the classification of cases according to type is given as recorded at the time of admission of the patient.

The recognition of tuberculoid leprosy as a separate type was adopted at the Leprosarium only five or six years ago, and consequently cases reported of this type are less in number and not comparable numerically with those of the other types which are reported for a period of fifteen years.

Table 7 shows the number of cases of each type admitted during the last fifteen years. Percentages of each type for this period are also calculated for comparison with the percentages reported in 1928. In both reports the percentage of cases of the mixed type almost equals the total percentage of lepromatous and neural cases, and in both reports are found a greater percentage of lepromatous than of neural cases.

FAMILY HISTORY OF LEPROSY

Patients admitted to the Leprosarium are usually reticent about disclosing their family relationship because of the fear that, should the information that leprosy existed in their families become generally known, the public knowledge would be detrimental to all their relatives. To avoid this cruel publicity⁷ patients in the Leprosarium often live under assumed names, and complete family histories are not always given. Such information as has been obtained, however, is not meager and leads to the conclusion often stated that leprosy is largely a family disease, occurring in closely related persons to an extent that suggests that either there is an inheritable familial predisposition or that the intimate contacts in family life account for the familial incidence. It seems to us probable that both factors play a part in the transmission of leprosy in families.

There were 147 patients with a family history of leprosy. Of these 74 had only one other member of the family afflicted with the disease, 42 had two, 17 had three, 11 had 4, 2 had five and 1 had eight other members of his family with leprosy. The family relationship of the contacts to the patients included 25 fathers, 24 mothers, 2 fathers-in-law, 64 brothers, 36 sisters, 4 sisters-in-law, 1 brother-in-law, 23 uncles, 9 aunts, 19 cousins and 7 grandparents.

In addition to the foregoing there were 24 children, 2 stepsons, 13 nephews and nieces and 7 grandchildren. For statistical purposes these cannot properly be considered as probable sources of family transmission of the disease, though the children and grandchildren might be considered from the point of view of hereditary predisposition.

Besides these there were 16 husbands and wives reported with leprosy, but these do not all indicate marital transmission, as, in all instances except two persons had the disease prior to marriage. In only a few instances of marital transmission, even prolonged and intimate, in the transmission of leprosy. From this view that leprosy is most

ected in childhood is accepted, and if it is in inherited predisposition plays an important role in familial transmission, the comparatively few cases of conjugal infection is readily

OCCUPATION

of patients previous to their admission one hundred and thirty different occupations occurred from common laborer to physician were in the unskilled labor group, but not larger than would be expected in the preponderance in normal community group. There were 123 patients in the collar group. As was stated in a previous report, the patients in the lower strata of social status, education, and income were not insured immunity against

MANIFESTATIONS

those in which a clear history of the disease is included in the statistics

was recalled as a macule or papule. The situation of the initial lesions was as follows: the face in 52 patients, the arms in 27, the elbows in 16, the legs in 47, the buttocks in 16, the ankles or feet in 7, and more widely distributed in 16, on the face and buttocks in 16, on the upper and lower limbs in 16, less generalized on

primary lesions by 193 patients, remembered by 90 patients, the nose being involved in 16, the body in 16, the knee by 1, the elbows by 5

as first lesions on the face and limbs on body and on the feet and areas by

the first complaint was numbness in the hands and feet in 23 and

symptom by 16, of the feet

There were 4 instances in which the patients reported a paresthesia or peculiar crawling sensation beneath the skin as the first symptom

Painful neuritis occurring in the limbs was stated to be the earliest indication of leprosy by 4 patients. Loss or thinning of the eyebrows was noted as the first evidence by 4 patients. Two patients reported anhidrosis of the hands and 1 anhidrosis of the feet as the initial manifestation

There were 26 patients who recalled a chronic nasal catarrh with bleeding, discharge, crust formation and blockage of the nares as their first symptoms. Chills and fever with the outcropping of the lesions similar to those of erythema nodosum was the mode of onset reported by 12 patients

There is no evidence in the histories of the sites of the initial macules and nodules that would indicate that any one region of the body was the probable port of entry for the infection. The diverse areas enumerated in which the first lesions appeared were the same as those for which the disease showed a predilection as it became more advanced and lesions increased in size and number

SEROLOGIC TESTS

There is no serologic test of value in the diagnosis of leprosy but tests intended for the detection of syphilis yield interesting results. That the Wassermann complement fixation reaction and the Kahn precipitation test are frequently positive in leprosy in the absence of syphilis is not sufficiently well recognized by the medical profession.⁹ It is not generally known that the serologic reaction is found to vary widely with the different types of the disease.

Table 8 gives the results in the Kolmer and Kahn reactions in different types of leprosy in the group of patients under study. The Kolmer and Kahn tests through long years of experience have been adopted in this institution because they were found to give the least number of false positive reactions in leprosy.

There are 178 patients in whom two to six Kolmer and Kahn tests were made during the course of institutional treatment. All tests were run by the same laboratory technician. It was observed that in the majority of cases the tests remained unchanged throughout the course of the disease, but in 69 patients there was either an increase or a decrease in the degree of the reaction in one or both serologic tests.

It is significant that these changes in serum reaction are closely correlated to changes in the clinical

⁹ Fox was one of the first in this country to point out that the Wassermann reaction is frequently obtained in cases of leprosy in the absence of syphilis. Fox H. The Wassermann Complement Fixation Test in Leprosy. *Am J Hyg* 1910.

the spread of the disease in those places, while the fact that from other regions few or no cases have been sent to the Leprosarium may be interpreted as showing that in other communities leprosy seldom, if ever, has occurred and that when it did occur it has shown no tendency to spread.

The accompanying chart illustrates graphically the yearly admissions of new cases and the average daily population for each year during the fifty years of existence of a leprosarium at Carville, La.

Table 1 shows the most notable shift in trend has been the increase in the number of cases from Texas, from which more cases have been admitted for the last period than from any other state and from which the annual

* This figure is the number of cases from Louisiana admitted from 1934 to 1938 and is not comparable with the figures in the same column from other states. During the period 1921 to 1928 107 patients were admitted from the state of Louisiana a yearly average of 14.57.

average of admissions is almost three times as great as it was for the first period. Johansen² states that there are four main foci of leprosy in Texas—Galveston, San Antonio, Brownsville and Corpus Christi. The number of admissions from Texas now exceeds the number from Louisiana. In former years the largest numbers of cases always came from Louisiana.

From California, New York, Florida and Illinois the average yearly number of admissions, though comparatively large, as may be seen in table 1 has been, like that of Louisiana, remarkably constant for each state for the two periods reported. In New York and Illinois the new cases may have been imported, but from Florida and California there were enough native born admissions to argue for an endemic origin.

In regard to the remaining states, there is not sufficient evidence to show a definite trend in any direction, it can however, be said that no trend toward the spread of leprosy in these states can be inferred from the small number of admissions to the Leprosarium. In Massa-

chusetts from which the yearly average declined from 2.42 to 0.40, and in Minnesota, with a decline of 0.85 to 0.13 there is reason to believe that the original foci established by imported cases have now disappeared or are rapidly disappearing.

Table 2 shows that from July 1928 to January 1944 the total number of foreign born patients admitted was 303 and that of this number 132 were born in Mexico. The latter number is greater than that of those born in any other foreign country and, considered with the increased number of cases from adjacent Texas, is significant in that it may indicate that much of the leprosy in Texas is directly or remotely of Mexican origin.

From the remaining foreign communities listed in table 2, the majority of patients came from the Philippines, the British West Indies, China, Russia, Hawaii, Puerto Rico and Cuba. In all these countries leprosy is indigenous, and it could well be that patients from them as well as from the other foreign countries where leprosy is prevalent, could have entered the United

States and become naturalized citizens while having leprosy in an unrecognizable stage.

Table 3 shows the states in which patients were born. A comparison of this table with table 1, which shows from which states patients were admitted, indicates that a number of patients born in one state have been admitted to the Leprosarium from another state, for instance, 176 patients were born in Louisiana but only 173 were admitted from that state. Three, therefore,

² Johansen, F. A. Leprosy as a Public Health Problem. Texas State J. Med. 35: 629 (Jan.) 1940.

departed from Louisiana and were admitted from other states

The difference between the number of patients born in a state and the number of patients admitted from that state is to some extent an indication of the tendency of leprosy to spread. In New York, for instance, with 2 native born admissions and 77 from other states or countries, there is little or no reason to believe that leprosy is endemic.³ Besides Louisiana, Texas with 125 native born, Florida with 34 native born and California with 23 native born are the other states in which leprosy shows a tendency to spread.

The figures from the state of Texas, which show 58 more patients admitted than were born in that state, are significant when correlated with the great number of patients of American birth but Mexican ancestry admitted from that state. The conclusion seems warranted that a fairly large percentage of these 58 persons contracted the disease in Mexico before their residence in Texas, even though its presence was not discovered until their sojourn in Texas.

Table 4 shows that there have been admitted more patients of Mexican ancestry than patients of other foreign descent. This is additional evidence that leprosy has been introduced from Mexico into Texas and California and, to a less extent, into some other states.

In Table 4 also is to be found evidence, in the large number of patients of Philippine, Chinese and Hawaiian

ancestry, that leprosy has been introduced directly or indirectly into California from the Philippines, China and Hawaii as well as from Mexico. There is also indication that leprosy has been introduced into Florida, New York and possibly some other Eastern and Southern states from the British West Indies, Cuba, Puerto Rico, Virgin Islands and some Latin American countries.

No admissions are reported of patients born in France, but there are reported 87 of French-Canadian ancestry. The immigrant Acadians, and not the immigrant French, are believed to have been one source of the spread of leprosy in Louisiana. It has been stated that the occurrence of leprosy has been traced back through generations to some of the original Acadian settlers.⁴ The continued occurrence of leprosy through many generations of Acadian descendants is considered strong evidence that leprosy is indigenous in Louisiana.

LEPROSY IN THE MILITARY SERVICE

Of significance as to the source from which leprosy is contracted is the different way in which soldiers of the last three wars were exposed to contagion and contracted the disease. There were admitted to the Lepro-

sarium 32 Spanish-American War veterans, 59 veterans of World War I and 10 veterans of World War II. As pointed out by Hasseltine,⁵ practically all Spanish-American War Veterans came from nonendemic states and contracted the disease while on military duty on such foreign soil as Cuba, the Philippines and other

countries in which leprosy is endemic. On the contrary, those World War I veterans in whom leprosy developed were enlisted into the armed forces from endemic areas in the United States and probably received their infection prior to their entry into military service, which was not to any great extent in countries in which leprosy was prevalent.

Admissions up to the present time of World War II veterans are, like those of World War I, from states or countries in which leprosy is endemic. Two patients were born in Louisiana, 2 in California, 2 in the Philippines, 2 in Texas, 1 in Mexico and 1 in Puerto Rico. Men in the present military service have not yet been exposed for a sufficiently long time for leprosy contracted in foreign fields to have developed, but the past experience of the Spanish-American War teaches that with the lapse of years, when the long incubation period of leprosy has come to an end, at least a small number of those who have served in countries where leprosy is prevalent will become its victims.

AGE

Table 5 gives the number of patients in each of nine age groups of one decade each. The age is that given at the time of admission and varies in individual cases from 4 to 84 years. The greatest incidence is seen in the twenties and thirties. The average age on admission is 35.5 years.

The average age at onset was computed at 30.4 years, which approximates remarkably closely the average of 30.2 calculated in the 1928 report.

TABLE 6—*Duration of the Disease Before Admission*

Less than 1 year	121	From 5 to 10 years	146
From 1 to 2 years	128	From 10 to 15 years	55

SEX

In the report made in 1928 there were 72.3 per cent males and 27.7 per cent females admitted to the Leprosarium. This percentage is approximately the same as that from almost all countries in which leprosy has been reported, and the incidence in males and females admitted to the National Leprosarium since 1928 is in nearly the same ratio, there were 499 males and 224 females admitted during the last fifteen years, a proportion again of more than two males to one female.

At variance with the almost universal rule of two male leprosy patients to one female patient is the exception found among the native born Negroes, of whom there were admitted 25 men and 27 women. Native born admissions of all races other than Negro showed 246 males and 122 females.

No satisfactory explanation is offered for the almost universal preponderance of males over females nor for the exception found in regard to the Negro race. A correct explanation perhaps would add important knowledge concerning the epidemiology of leprosy. The number of our cases is so small that conclusions should not be drawn from them, but similar findings of an equal incidence in the sexes have been reported by Saunders and Guinto⁶ in a field study of leprosy in the Virgin Islands. They cite surveys in Nigeria by Davey and in the Belgian Congo by Degotte, which also showed that prevalence in the sexes was very nearly equal in those countries. It will be noted that the

exceptions cited to the rule of incidence in the different sexes have all occurred either in foreign countries with predominating Negro populations or in the United States in the Negro race.

TYPES OF LEPROSY

For the purpose of this report, the classification of cases according to type is given as recorded at the time of admission of the patient.

The recognition of tuberculoid leprosy as a separate type was adopted at the Leprosarium only five or six years ago, and consequently cases reported of this type are less in number and not comparable numerically with those of the other types which are reported for a period of fifteen years.

Table 7 shows the number of cases of each type admitted during the last fifteen years. Percentages of each type for this period are also calculated for comparison with the percentages reported in 1928. In both reports the percentage of cases of the mixed type almost equals the total percentage of lepromatous and neural cases, and in both reports are found a greater percentage of lepromatous than of neural cases.

FAMILY HISTORY OF LEPROSY

Patients admitted to the Leprosarium are usually reticent about disclosing their family relationship because of the fear that, should the information that leprosy existed in their families become generally known, the public knowledge would be detrimental to all their relatives. To avoid this cruel publicity⁷ patients in the Leprosarium often live under assumed names, and complete family histories are not always given. Such information as has been obtained, however, is not meager and leads to the conclusion often stated that leprosy is largely a family disease, occurring in closely related persons to an extent that suggests that either there is an inheritable familial predisposition or that the intimate contacts in family life account for the familial incidence. It seems to us probable that both factors play a part in the transmission of leprosy in families.

There were 147 patients with a family history of leprosy. Of these 74 had only one other member of the family afflicted with the disease, 42 had two, 17 had three, 11 had 4, 2 had five and 1 had eight other members of his family with leprosy. The family relationship of the contacts to the patients included 25 fathers, 24 mothers, 2 fathers-in-law, 64 brothers, 36 sisters, 4 sisters-in-law, 1 brother-in-law, 23 uncles, 9 aunts, 19 cousins and 7 grandparents.

In addition to the foregoing there were 24 children, 2 stepsons, 13 nephews and nieces and 7 grandchildren. For statistical purposes these cannot properly be considered as probable sources of family transmission of the disease, though the children and grandchildren might be considered from the point of view of hereditary predisposition.

Besides these there were 16 husbands and wives reported with leprosy, but these do not all indicate marital transmission, as, in all instances except two couples, both persons had the disease prior to marriage.

The comparatively few instances of marital transmission indicate that contact, even prolonged and intimate, is not the only factor in the transmission of leprosy. If the widely entertained view that leprosy is most

6 Saunders G. M. and Guinto R. S. A Field Study of Leprosy in the Virgin Islands. *Internat. J. Leprosy* 10: 20 (Dec.) 1942.

8 Leper Loose Time 42: 46 (Dec. 6) 1943.

easily contracted in childhood is accepted, and if it is granted that an inherited predisposition plays an important part in familial transmission, the comparatively small number of cases of conjugal infection is readily explained

OCCUPATION

Employments of patients previous to their admission were listed under one hundred and thirty different occupations, which varied from common laborer to physician. A large majority were in the unskilled labor group, but this majority was not larger than would be expected from the numerical preponderance in normal communities of persons in this group. There were 123 patients classed in the white collar group. As was stated in a previous report advantages in social status, education, wealth and culture has not insured immunity against leprosy.

INITIAL MANIFESTATIONS

Not all cases, but only those in which a clear history of the onset was obtained are included in the statistics that are now presented.

The first manifestation was recalled as a macule or macules by 259 patients. The situation of the initial macule or macules was on the face in 52 patients, the neck in 4, the body in 29, the arms in 27, the elbows in 2, the wrists or hands in 5, the legs in 47, the buttocks or hips in 9, the knees in 14 and the ankles or feet in 7.

Macules, more numerous and more widely distributed, were remembered as occurring as first lesions on the face and body by 5 patients, on the face and buttocks by 10, on the body and limbs by 16, on the upper and lower limbs by 21, and more or less generalized on various parts of the body by 11.

Nodules were remembered as primary lesions by 193 patients. Of these the face was remembered by 90 patients as being the first site affected, the nose being primarily involved in 14. The ear lobes were reported as the location of first nodules by 4 patients, the body by 7, the buttocks by 1, the legs by 18, the knee by 1, the ankles and feet by 4, the arms by 9, the elbows by 5 and the wrists and hands by 8.

Nodules in multiple sites were recalled as first lesions on the face and body by 4 patients, on the face and limbs by 18, on upper and lower limbs by 15, on body and limbs by 1 and on more or less generalized areas by 8 patients.

Numbness of the hands and feet was the first complaint of 77 patients. Of these 12 first noticed numbness of the fingers, the little and ring fingers being usually the first to be involved. Numbness of the hands and forearms was the first symptom noticed by 23 and numbness of the feet and legs by 42.

Painless burns were noted as the initial symptom by 14 patients—of the fingers or hands by 9, of the feet or legs by 3, of the forearms by 1 and of the elbow by 1.

Swelling of the feet and hands was the mode of onset reported by 23 patients. Swelling of the feet occurred primarily in 7, swelling of the feet and legs in 3, swelling of the hands in 4 and swelling of the hands and feet in 9.

Blisters were the earliest manifestation of leprosy reported by 11 patients, blisters on the fingers or hands being noted by 4, blisters on the feet or toes by 5 and blisters on both hands and feet by 2.

Plantar tropic ulcers were said to be the initial lesion by 5 patients.

There were 4 instances in which the patients reported a paresthesia or peculiar crawling sensation beneath the skin as the first symptom.

Painful neuritis occurring in the limbs was stated to be the earliest indication of leprosy by 4 patients. Loss or thinning of the eyebrows was noted as the first evidence by 4 patients. Two patients reported anhidrosis of the hands and 1 anhidrosis of the feet as the initial manifestation.

There were 26 patients who recalled a chronic nasal catarrh with bleeding, discharge, crust formation and blockage of the nares as their first symptoms. Chills and fever with the outcropping of the lesions similar to those of erythema nodosum was the mode of onset reported by 12 patients.

There is no evidence in the histories of the sites of the initial macules and nodules that would indicate that any one region of the body was the probable port of entry for the infection. The diverse areas enumerated in which the first lesions appeared were the same as those for which the disease showed a predilection as it became more advanced and lesions increased in size and number.

SEROLOGIC TESTS

There is no serologic test of value in the diagnosis of leprosy, but tests intended for the detection of syphilis yield interesting results. That the Wassermann complement fixation reaction and the Kahn precipitation test are frequently positive in leprosy in the absence of syphilis is not sufficiently well recognized by the medical profession.⁹ It is not generally known that the serologic reaction is found to vary widely with the different types of the disease.

Table 8 gives the results in the Kolmer and Kahn reactions in different types of leprosy in the group of patients under study. The Kolmer and Kahn tests through long years of experience have been adopted in this institution because they were found to give the least number of false positive reactions in leprosy.

There are 178 patients in whom two to six Kolmer and Kahn tests were made during the course of institutional treatment. All tests were run by the same laboratory technician. It was observed that in the majority of cases the tests remained unchanged throughout the course of the disease, but in 69 patients there was either an increase or a decrease in the degree of the reaction in one or both serologic tests.

It is significant that these changes in serum reactions were closely correlated to changes in the clinical

⁹ Howard Fox was one of the first in this country to point out that a positive Wassermann reaction is frequently obtained in cases of leprosy in which there is no history or symptom of syphilis. Fox, H. The Wassermann and Noguchi Complement Fixation Test in Leprosy. *Am J M Sc* 139: 725 (May) 1910.

manifestations of the disease. We believe that this argues for the presence in the serum of leprosy patients of a reagin which reacts positively with Kolmer or Kahn antigen in the absence of syphilis. These figures confirm the previous findings of Badger¹⁰ in this respect and are reported elsewhere in detail.¹¹

TREATMENT

All patients with few exceptions received some type of treatment directed against leprosy. More or less routine treatments consisted of chaulmoogra oil given by mouth and intramuscularly, the iodized esters of hydnocepus intramuscularly, solution of potassium arsenite by mouth cod liver oil in varying doses, vitamins in various combinations and strychnine sulfate.

Experimental treatments included gold sodium thio-sulfate, mercurochrome intravenously, smallpox vaccine, hirudin fever therapy in the Kettering hyperthermia cabinet, diphtheria toxoid, sulfanilamide, sulfathiazole, sulfapyridine, sulfadiazine, promin, Internal Antiseptic 307, diasone, pooled human plasma, Karwinskia latifolia and penicillin. None of the experimental treatments proved specific but best results with least harmful effects were produced by promin¹² and diasone.

Until a more specific drug can be developed, general hygienic measures including institutional and nursing care, physical therapy, judiciously adjusted hours of rest and outdoor exercise and especially a well balanced nutritious diet must continue to play an important role in overcoming the disease.

DURATION OF LEPROSY

For all the types of leprosy combined, the average duration of the disease from the time of its onset until death was estimated at 10.3 years for those patients under study who died in the hospital during the period covered by this report. This estimate is approximately four years less than that calculated for the 1928 report, but the shorter period of observation, fifteen years in comparison to 34 years, explains this difference.

Duration of life after contracting the disease varied in the different types of leprosy as follows: neural cases

TABLE 9.—Disposition of Patients

Types of Disease	Paroled Patients				Absconded Patients			Deaths	Patients Remaining in Hospital (1928-1943)
	Number of Cases	Discharged Disease Arrested	Remaining in Hospital, Disease Arrested	Readmitted Disease Relapsed	Total	Readmitted to Hospital	Aliens Deported to Native Country		
Mixed	379	19	3	5	51	94	13	117	161
Lepromatous	208	16	2	2	42	19	13	62	108
Neural	100	90	9	8	13	3	0	20	46
Tuberculoid	31	20	2	0	6	2	0	1	9
Total	723	145	16	16	111	48	30	100	324

14.5 years, mixed cases 10.6 years and lepromatous cases 9.3 years. In tuberculoid cases there was only one death eighteen years after onset.

The average duration of life in the different types shows, as do other figures in regard to type, that the best prognosis is in the tuberculoid type and that the prognosis is better in the neural cases than it is in either the lepromatous or the mixed cases.

DISPOSITION OF PATIENTS

Table 9 shows that 145 of the 723 patients hospitalized, or 20 per cent, have been paroled as having the disease in an arrested form and being no longer a menace to public health.

Criteria in this institution for parole are twelve consecutive monthly negative bacterioscopic examinations of cutaneous and nasal smears and an inspection by the medical staff to determine whether or not there are any visible or palpable signs that the disease is still active.

The better or worse prognosis in the different types of the disease show clearly in the percentages of each type paroled, in the percentages of relapsed paroled patients and in the percentages of deaths occurring in each type.

Table 10 shows the primary causes of the 190 deaths occurring in the Leprosarium among the 723 patients included in this study. The mortality rate was 26.7 per cent, but leprosy was responsible for only a small percentage of the deaths. While nephritis and tuberculosis were the direct cause of almost half the fatalities, it is probable that leprosy was responsible for the occurrence of these two diseases and that the lepromatous and mixed types were more prone to develop these fatal complications than was the neural type. Necropsies confirming the primary cause of death were performed in 75.3 per cent of deaths.

At present there are remaining in the Leprosarium 324 patients who were originally admitted subsequent to July 1, 1928, the date on which the period of the

present study commenced. Of these patients there are 16 in whom the disease is arrested but who have elected to remain in the hospital or have returned after conditional release because of disabilities resulting from leprosy which prevent their gaining a livelihood and because they have no home to which to go nor the means to live elsewhere. That none of these patients have relapsed in spite of continuous exposure to infection can be interpreted as a hopeful sign that the disease can be eradicated, at least in some cases, and that it is possible thereafter for a permanent resistance to leprosy to be established.

SUMMARY

This report is based on data accumulated during the last fifteen years from 723 patients in the National Leprosarium. The Leprosarium does not continuously hospitalize any but citizens of the United States. The foreign born patients admitted are either naturalized citizens or subject to immigration regulations and deportation. Of the total number of patients 303 are foreign born and 420 native born. Of the foreign born more than 72 per cent are of Mexican, Philippine, British West Indies or Chinese nativity. Many of these probably had contracted the disease before their arrival in the United States and may have established foci which could account for the occurrence of some of the cases in native born citizens, especially in Texas, California and Florida.

From Texas the average yearly admissions are 12.2, nearly three times as many as formerly and greater than from any other state.

From Louisiana the average yearly admissions are 11.53, a little less than formerly but greater than from any other state except Texas. Formerly the admissions from Louisiana exceeded those from Texas.

From California and Florida there are enough admissions of native born to argue for an endemic origin, but there are also evidences of imported cases.

From New York and Illinois there are not enough natives of these states admitted to establish evidence of an endemic origin. Almost all cases are probably imported.

From Minnesota and Massachusetts the decline in admission warrants the belief that leprosy is not indigenous in those states and the foci established by immigration have disappeared or are rapidly disappearing.

Thirty-two Spanish-American War Veterans have been admitted, all of whom presumably contracted the disease in foreign countries in which leprosy is endemic.

Fifty-one veterans of World War I have been admitted who probably were infected before their induction into the Army.

Ten veterans of World War II have been admitted who were enlisted from endemic areas in the United States or were born in the Philippines, Mexico or Puerto Rico and presumably contracted the disease before their induction.

It is safe to predict from the experience of the Spanish-American War that a small number of those who serve in the armed forces in foreign countries where leprosy is prevalent will become its victims.

The average age on admittance is 35.5 years, and the greatest incidence is in the twenties and thirties.

The average age at onset of the disease is 30.4 years.

The duration of the disease before admission is from a few weeks to over forty years and averages five years.

The incidence in Louisiana of leprosy in the white race as estimated from admissions to the Leprosarium is twice that in the Negro race.

The proportion, including all races, of males to females is more than two to one.

There is not the usual proportion of two males to one female in the Negro race, there are approximately an equal number of Negro men and women.

The number of cases of the mixed type of leprosy almost equals the total of lepromatous and neural cases, and there are more lepromatous than neural cases.

There are 147 patients with a family history of leprosy, including 25 fathers, 24 mothers, 64 brothers, and 35 sisters and others less closely related.

The small number of cases in which there may have been marital transmission (only two couples) seems to indicate that contact is not the sole requisite for the transmission of leprosy.

No evidence is disclosed that any occupation is a predisposing cause. The employments of patients previous to admission are listed under one hundred and thirty different occupations, some of high and some of low rank in the social scale.

The first lesion is described as a macule by 259 patients and a nodule by 193. Both lesions occur primarily on regions that later are to be the sites of predilection for the eruption in the advanced stage of the disease. No probable port of entry is disclosed by the situations of the first lesions.

Other patients report sensory disturbances, of which anesthesia is the most common, as the earliest manifestations, a few recall blisters, painless burns and plantar ulcers, and some remember symptoms less characteristic of leprosy.

The usually employed serologic tests are of no value in the differentiation of leprosy from syphilis but are of value as an index of the prognosis and of the progress of leprosy.

During the period of study among the numerous experimental treatments investigated promin and diosone prove to be the most beneficial.

The average duration of life after the onset of leprosy is calculated as 10.3 years, but this average is derived from individual cases and is limited to a group of patients during a fifteen year period. In the tuberculoid type there is only one death eighteen years after the onset of leprosy. The duration from onset to death is longer in the neural cases than in either the lepromatous or the mixed cases.

Twenty per cent of the 723 patients admitted have been released conditionally as having the disease in arrested form and being no longer a menace to public health.

No patient with the tuberculoid type relapsed, but 9 per cent with the neural type, 12.5 per cent with the lepromatous type and 26 per cent with the mixed type relapsed.

In the table showing the causes of deaths it is seen that leprosy directly is responsible for only a small percentage of the deaths, while nephritis and tuberculosis are the direct cause of almost half of the fatalities.

"GAMMA GLOBULIN" AND "PLACENTAL GLOBULIN"

A COMPARISON OF THEIR EFFECTIVENESS IN THE PREVENTION AND MODIFICATION OF MEASLES

MORRIS GREENBERG, MD

SAMUEL FRANT, MD

AND

DAVID D RUTSTEIN, MD

NEW YORK

Three agents are currently recommended for the prophylaxis of measles—convalescent human serum, placental globulin (immune globulin-human) and gamma globulin derived from normal human serum (human immune serum globulin). Concentrated, pooled ascites fluid¹ has also been suggested but has not come into general use and will not be discussed here. The prophylactic effectiveness of convalescent serum has been recently summarized in a well controlled study of 502 household contacts between the ages of 6 months and 15 years by Stillerman, Marks and Thalhimer.² These authors obtained complete protection in 50 per cent modified measles in 49 per cent and regular measles in 1 per cent of the individuals studied. While the effectiveness of convalescent serum is not questioned its lack of ready availability and the comparatively large doses which are necessary make its use impractical. This study is directed toward the comparison of the effectiveness and incidence of untoward reactions of the remaining two agents—placental globulin (immune globulin-human) and normal human serum gamma globulin (human immune serum globulin). The characterization of normal human serum gamma globulin (human immune serum globulin) has been published by Cohn and his co-workers.³ This material will be referred to hereafter in this paper as gamma globulin. Placental globulin (immune globulin-human) will hereafter be referred to as placental globulin.

In evaluating the literature on the prophylaxis of measles, those studies in which household contacts were used are the most significant. The smaller number of secondary cases occurring following the casual exposure of contacts in hospitals, schools or playgrounds, compared with the larger number occurring among those intimately exposed in the home has been

pointed out by a number of observers⁴ and has been particularly stressed by Karelitz and Schick.⁵ The latter authors also pointed out that the contact is more intimate in the homes of the poor than in the homes of the well-to-do.

The use of immune globulin obtained from human placenta in the prophylaxis of measles was first introduced by McKhann and Chu⁶ in 1933. In one of his later papers McKhann⁷ analyzed a group of 2,704 contacts in whom the exposure was both casual and intimate. Two groups of contacts were said to be intimately exposed, but no statement was made indicating place of exposure. One of these groups, totaling 585 cases, was given placental globulin for protection, the other group of 1,263 cases for modification. The exact doses and time of injections were not given, but it would appear from the text that in the latter group the doses, ordinarily effective for prevention when given early in the incubation period, were injected on the eighth day following initial exposure to obtain modification. When the results of the two groups were combined, there was obtained complete protection in 48.5 per cent, modification in 44.4 per cent and failure in 7 per cent. Reactions occurred in somewhat less than half the cases and were severe in approximately 5 per cent. Karelitz, Greenwald and Klein⁸ treated 64 contacts exposed in homes with good hygiene with 10 to 20 cc of placental globulin on the second to fifth day of exposure. Protection was obtained in 40 per cent, modification in 48 per cent and failure in 12 per cent. Among the 64 cases there were 34 severe reactions, of which 8 were general and 26 local. In a study conducted by the Chicago Department of Health⁹ a group of 678 household contacts under the age of 10 were treated with placental globulin in doses of 2 to 3.35 cc. Complete protection was obtained in 52.1 per cent, modification in 43.2 per cent and failure in 4.7 per cent. More than 60 per cent of the children injected were under 1 year of age in whom there would still be some inherited passive immunity. Blossom¹⁰ reported the results in private practice of a study of 107 children, most of whom were between the ages of 1 and 8, who were exposed either in their homes or in the bus going to and from school and who were injected with 2 cc of placental globulin during the period from the fifth to the ninth day after exposure. Measles developed in 31.8 per cent, among whom it was mild in 68 per cent, moderate in 29 per cent and severe in 3 per cent. Reactions occurred in 95 per cent of the total group, 81 per cent of which were mild and 14 per cent severe.

Two reports on the prophylactic use in measles of gamma globulin have appeared. Stokes, Maris and

Dr. William Thalhimer put his experience at our disposal and gave valuable aid in planning the investigation.

From the Bureau of Preventable Diseases and the Bureau of Laboratories, Department of Health, City of New York.

The physicians of the Bureau of Preventable Diseases of the New York City Department of Health performed the field work in this study and followed up the contacts.

The American National Red Cross cooperated in this study in order to determine the effectiveness of gamma globulin in the prophylaxis of measles on a community basis.

The products of plasma fractionation employed in this work were developed from blood collected by the American Red Cross by the Department of Physical Chemistry, Harvard Medical School, Boston, under a contract recommended by the Committee of Medical Research between the Office of Scientific Research and Development and Harvard University. Dr. Edwin J. Cohn and Dr. J. L. Oncley of the Department of Physical Chemistry and Dr. Charles A. Janeway of the Department of Pediatrics of Harvard Medical School gave their cooperation.

Gellis¹¹ reported the results of prophylaxis with gamma globulin in 891 household contacts of all ages in the private practice of a number of physicians. They obtained 71.4 per cent protection and 28.6 per cent modification, using doses between 0.5 and 5.0 cc. Ordman, Jennings and Janeway¹² used a dose of 2 cc for infants between the ages of 6 months and 1 year, 2.5 cc for children between 1 and 5 years and 5 cc for children over 5 years of age. In 139 household contacts among underprivileged families in Boston they obtained complete protection in 71 per cent, modification in 27 per cent and typical measles in 2 per cent.

PLAN OF STUDY

Gamma globulin and placental globulin were studied under the same conditions in household contacts of similar age distribution (table 1) and at similar periods following exposure to the source case (table 2). The contacts were all in the age group from 6 months through 6 years, most of whom were between the ages of 6 months through 3 years (table 1). All contacts were known not to have had measles previously, and therefore all contacts referred to in this study are considered to be susceptible contacts.

All contacts were seen by physicians trained in the diagnosis of acute communicable disease on the staff of the New York City Department of Health. Private physicians reporting cases of measles were interviewed by one of these physicians questioned about the number and ages of household contacts and an offer of gamma globulin or placental globulin for passive immunization of contacts was then made to them. They were advised that the injections of the material might be given by them or if they preferred by physicians of the department of health. The offer was conditioned by permission from the private physician to the physician of the department of health to visit and examine the source case and to make follow-up visits to the contacts for a period of twenty-one days following the first exposure. Where there was no physician in attendance the offer was made directly to the parents. As soon as a case of measles was reported and the offer of immunization of contacts was accepted by the physician or parents, the physician of the department of health visited the home, examined the source case and completed a form on which were listed the name, age, sex and home address of the patient as well as the presence or absence of coryza, conjunctivitis, rash (with date of onset), Koplik spots and fever. In addition there were listed the names and ages of all household contacts, and a note was made on the degree and adequacy of isolation of the case. If the diagnosis of a primary case was confirmed, the gamma globulin or placental globulin was injected subcutaneously into the contacts or, where arrangements had been previously made, the material was left at the home for injection that day by the private physician. A separate form was then made out for each household contact injected on which were listed the name, age, address, sex and relationship of the contact, the nature, the lot number and amount of material used, the date of injection, the symptoms of measles, if any, and the date of appearance of the rash in the source case.

In 49 per cent of homes economic conditions were such that no attempt could be made to carry out any sort of isolation in the primary case. Furthermore, all children with primary measles remained at home so that there were frequent opportunities for contact between them and the other children of the family. Since diagnosis was rarely made before the appearance of the rash, which is considered in this study to be the fourth day of illness, there was continuous contact between the patient and the contacts for at least four days of the period of greatest communicability even in those homes where attempts were made to isolate the contacts after the diagnosis had been made. All the contacts studied were exposed to cases in the same household. Those contacts living in the same house but not in the same household as the source case were excluded.

TABLE 1—Percentage Distribution of Children Injected with Gamma Globulin and with Placental Globulin by Age

Age	Gamma Cases	Globulin, per Cent	Placental Cases	Globulin per Cent

Totals	814	100.0	90	100.0

Follow-up visits were made by the physicians of the department of health two days after the appearance of the rash in the source case to rule out primary measles in the contact. The next visit was made seven days after the appearance of the rash in the source case and thereafter visits were made every other day until the seventeenth day after the appearance of the rash in the source case. Since the rash usually occurs on the fourth day after onset of symptoms it was considered that the contacts were followed for twenty-one days after the onset of the disease in the source case. If no measles developed by that time, the follow-up was terminated and the contact was considered to have been completely protected. If measles developed in a contact, the physician revisited once or twice to determine the degree of severity of symptoms and to complete the form. The date of onset of measles in the contact was noted and the severity of measles was evaluated (modified from the classification of Stillerman, Marks and Thalheimer²) on the basis of the severity of four symptoms: (1) coryza and conjunctivitis, (2) cough, (3) fever and (4) rash. Each of these symptoms was divided into three categories, A, B and C. For coryza and conjunctivitis, A represented mild

The Use of Concentrated Normal Human Serum Gamma Globulin (Human Immune Serum Globulin) in the Prophylaxis and Treatment of Measles. *J. Clin. Investigation* 23: 531-540 (July) 1944.
12 Ordman, C. W., Jennings, C. G. and Janeway, C. A. Chemical, Clinical and Immunological Studies on the Products of Plasma Fractionation. XI. The Use of Concentrated Normal Human Serum Gamma Globulin (Human Immune Serum Globulin) in the Prevention and Attenuation of Measles. *J. Clin. Investigation* 23: 541-549 (July) 1944.

B moderate and C severe redness and discharge. For cough, A indicated occasional, B moderate and C frequent cough. For fever, A represented a temperature of 99 to 101 F, B 101 to 102.5 F and C 102.5 F and higher. For the rash, A signified occasional lesion, B a moderate number of scattered spots and C a generalized rash. To obtain a quantitative value for mild, moderate and severe measles, all A's were given a numerical value of 1, all B's a value of 2 and all C's a value of 3. The disease was considered mild if the sum of the values did not exceed 6, moderate if the sum was 7 or 8 and severe if the sum was 9 or over.

In the cases of gamma globulin the material in solution at a concentration of twenty-five times that of pooled adult serum from which it was derived was rebottled in the Bureau of Laboratories of the New York City Department of Health so that each vial contained 2 cc.¹³ The dose for each case was the total contents of the vial. The same dose was used for all contacts regardless of age (6 months through 6 years). In the case of placental globulin the material was distributed in 5 cc vials¹⁴ and the total contents of the vial were injected into each contact. A total of 814 household contacts were injected with gamma globulin and 90 contacts were injected with placental globulin.¹⁵

TABLE 3—Comparison of Gamma Globulin and Placental Globulin in Prophylaxis of Measles in Household Contacts

Material Used	Number Injected	No Measles		Mild Measles		Moderate Measles		Severe Measles	
		No	%	No	%	No	%	No	%
Gamma globulin	814	641	78.7	160	19.7	13	1.6	0	0
Placental globulin	90	35	38.9	74	26.6	10	11.1	21	23.3

RESULTS OF THE STUDY

Among the 814 contacts injected with 2 cc of gamma globulin 641, or 78.7 per cent, did not develop measles, 160, or 19.7 per cent, developed mild measles and 13, or 1.6 per cent, developed moderate measles. None developed severe measles. In contrast, among 90 receiving 5 cc of placental globulin 35, or 38.9 per cent, did not develop measles, 24, or 26.6 per cent, developed mild measles, 10, or 11.1 per cent developed moderate measles, and 21, or 23.3 per cent, developed severe measles (table 3). It will be noted that the results obtained with gamma globulin are significantly better than those obtained by the use of placental globulin.

Among the 814 contacts injected with gamma globulin, reactions occurred in 7, or less than 1 per cent of the group. Two of the reactions were general, consisting of fever which rose on the day following injection to 104 F in one and to 100 F in the other. The five local reactions consisted of slight induration about the site of the injection, which lasted a few hours. In contrast, among the 90 cases in which placental globulin was administered, reactions occurred in 37, or 41 per cent. There were 18 general reactions, 10 of these

consisting of anorexia, restlessness and sleeplessness and 8 with the aforementioned symptoms plus fever, under 101 degrees F in 3 and over 103 F in 5. Local reactions occurred in 23 and consisted of pain, swelling, redness and induration about the site of the injection, lasting from one to two days.

TABLE 4—Results of Immunization with 2 Cc of Gamma Globulin by Age

Age	Number Injected	No Measles		Mild Measles		Moderate Measles	
		No	%	No	%	No	%
6-9 months	86	84	97.6	2	2.3	0	0.0
9-12 months	84	77	91.7	6	7.1	1	1.1
1 year	230	180	80.0	44	18.0	3	1.3
2 years	160	132	78.1	35	20.7	2	1.2
3 years	120	92	77.3	35	27.1	2	1.6
4 years	61	39	64.0	19	31.2	3	4.9
5 years	41	25	61.0	15	36.5	1	2.4
6 years	8	3	37.5	4	50.0	1	12.5
Total	814	641	78.7	160	19.7	13	1.6

The result of the immunization of gamma globulin was analyzed by age (table 4). It will be noted that the older the child, the less the degree of complete protection. The high degree of complete protection obtained by infants under 1 year of age probably represents a combination of passive immunization acquired from the mother and passive immunization artificially conferred by the gamma globulin. The drop in protection in the older children might be explained by the fact that a constant dose of gamma globulin was given regardless of body weight. This is probably a desirable situation, since the experimental dosage attempted in this study conferred complete protection on infants and small children and tended toward modification in the case of the older children.

It is of interest to compare these results with an additional 38 similar contacts with similar age distribution who were injected with 1 cc of gamma globulin. In this group 20, or 52.6 per cent, were completely protected, 11, or 28.9 per cent, developed mild measles, 6, or 15.8 per cent, developed moderate measles and 1, or 2.7 per cent, developed severe measles.

TABLE 5—Results of Immunization with 2 Cc of Gamma Globulin by Day of Exposure on Which Injection Was Made

Day of Exposure on Which Injection Was Made	Number Injected	No Measles		Mild Measles		Moderate Measles	
		No	%	No	%	No	%
1st	0	0	0.0	0	0.0	0	0.0
2d	2	1	50.0	1	50.0	0	0.0

Total	814	641	78.7	160	19.7	13	1.6

In table 5 the results of immunization of the 814 contacts given gamma globulin were analyzed by day of injection following first exposure to measles. If those injected on the second, ninth and tenth days are excluded from consideration because of the small number of cases in those categories, it will be noted that there is no significant difference in the amount of complete protection obtained after the injection of gamma globulin from the third to the eighth day following initial exposure.

13 The vials actually contained 2.2 cc to allow for loss on withdrawal of material from the vial.

14 The placental globulin in part was obtained from a commercial source and in part from a noncommercial source.

15 This experiment was performed in part (171 injected contacts) with five experimental lots of gamma globulin each of which was prepared in a slightly different manner from that of the standard lots. In four of these experimental lots (147 injected contacts) results were similar to those obtained with standard lots and are included in the report. One of these lots (S11) produced results quite different from that of the remaining lots and those results are not included in the tabulation. The results obtained with this lot are as follows: 24 contacts were injected, 16 did not develop measles, 4 developed mild measles, 1 moderate measles and 3 severe measles.

In evaluating the results obtained by prophylactic materials, it is necessary to know the secondary attack rate of household contacts to cases when no immunizing procedures are used. The rate in measles has been shown to be fairly uniform in different communities, particularly for ages under 14. Stillerman and Thalheimer¹⁶ have listed the secondary attack rate of regular measles among susceptible contacts as reported in the literature and have added rates of their own. From their table we have calculated the secondary attack rates for children up to the age of 7, from the figures of Chapin in Providence, R. I., 88 per cent (1917-1923), Wilson in Providence, R. I., 88 per cent (1929-1934), Fales in Baltimore, 82 per cent (1936-1937), Top in Detroit, 80 per cent (1935) and Butler in Wilesden, England, 84 per cent (1908-1911). In the age group under 7 Stillerman and Thalheimer obtained a rate of 78 per cent in New York City.

In this study all family contacts from 6 months through 6 years of age whose physician or parents refused to have them inoculated were followed in the same fashion by the same personnel as the contacts receiving prophylaxis. Among 65 such contacts 54 developed measles, an attack rate of 83 per cent, which is similar to the secondary attack rates as calculated from the summaries of Stillerman and Thalheimer¹⁶. Among those 54 cases the measles was mild in 11, or 20 per cent, moderate in 12, or 22 per cent and severe in 31, or 57 per cent. It is evident that the results obtained in this study, particularly with the use of gamma globulin, are strikingly different from the secondary attack rates of measles in this age group when no prophylactic agent is used.

COMPARISON OF THE PHYSICOCHEMICAL AND IMMUNOLOGIC CHARACTERISTICS OF GAMMA GLOBULIN AND PLACENTAL GLOBULIN¹⁷

In table 6¹⁸ it is evident that the concentration and total amount of gamma globulin and the titers of the various immunologic tests performed show that the lots of gamma globulin used in the study had a consistently higher potency than the lot of placental globulin tested. Since there is no laboratory method for determining the concentration of measles antibody, it is not possible to make a direct comparison between the clinical results obtained in this study and the laboratory studies of the materials. However, since the concentration and the amount of gamma globulin and the concentration of all the other antibodies studied are consistently less in the placental globulin, the concentration of measles antibody might also be expected to be less in the placental globulin.

COMMENT

The morbidity of measles has not declined over the years, as has that of diphtheria. In New York City in 1941 there were 80,000 cases reported, more cases than in any previous year. Although there has been a decline in mortality, deaths still occur. For the five year period 1939-1943 there were 49 deaths in New York City, 80 per cent of which occurred in the first five years of life. These statistics suggest that in the

absence of an effective active immunizing agent, passive prophylaxis should be administered to household contacts during the first five years of life.

Since convalescent serum is not generally available, and the dosage required is large, the results of this study would indicate that gamma globulin is the agent of choice in the prophylaxis of measles. Gamma globulin can be produced in large quantities, it confers adequate protection in small doses and the number of untoward reactions is minimal. Further studies are needed to determine the minimal protective or modifying dose in each age group.

SUMMARY AND CONCLUSIONS

1. Gamma globulin was administered in a uniform dose of 2 cc to 814 household contacts (between the ages of 6 months through 6 years) of cases of measles. None developed regular measles, 78.7 per cent were completely protected and 21.3 per cent had modified measles. Among those cases of modified measles,

* Immunologic measurements are expressed as a ratio of the titer of the solution to the titer of reference lot IIG-66 of human immune serum globulin¹⁸ the value for lot IIG-66 being considered as one.

† Data on human immune serum globulin is presented in terms of the range of determinations in the various lots used (lots IIG-84, IIG-74B, IIG-120, IIG-2, L371, S-1, S-4 and U-874²).

‡ Lot number 41 (Immune Globulin Human).

92 per cent were mild measles and 8 per cent moderate measles. There was a tendency for the effectiveness to decrease with age, but the amount of complete protection was not affected by the day of exposure on which the injection was made from the third to the eighth day following initial exposure to the original case. Untoward reactions were rare.

2. Placental globulin was injected into 90 similar contacts in a dose of 5 cc. Severe measles occurred in 23.3 per cent, 38.9 per cent were completely protected and 37.7 per cent had modified measles. Among the cases of modified measles 70 per cent were mild and 30 per cent were moderate. Reactions occurred in 41 per cent of those injected.

3. In a group of 65 contacts of similar age distribution who received no prophylaxis 54, or 83 per cent developed measles. Of these 31 per cent were severe, 12 moderate and 10 mild. This experience is consistent with that of similar groups reported elsewhere.

4. Physicochemical and immunologic studies of gamma globulin and placental globulin demonstrated that gamma globulin is the more potent of the two agents.

5. Gamma globulin (human immune serum globulin) is the material of choice in the prophylaxis of measles.

TREATMENT OF HUMAN ANTHRAX
WITH PENICILLIN

REPORT OF THREE CASES

FRANKLIN D MURPHY, M D
ALFRED C LA BOCCETTA, M D
AND
JOHN S LOCKWOOD, M D
PHILADELPHIA

Human anthrax, although not a widespread disease continues to be an important medical problem among workers in the wool and leather industries. The introduction of more rational and effective methods of prophylaxis and treatment have lowered the incidence and death rate in anthrax but the disease continues to carry a significant mortality. In the five year period 1938 to 1942, exclusive of West Virginia, there were 390 cases of human anthrax reported in the United States, with a mortality rate of 13.8 per cent, which compares favorably with a mortality rate of 15.1 per cent during the period 1933 to 1937 and which represents a distinct advance over the period 1928 to 1932, when among 394 reported cases 106, or 26.8 per cent, ended fatally.¹

The epidemiology and prophylaxis of anthrax, which are important problems in industrial hygiene, are discussed in great detail in the report of the symposium on anthrax² held by the Department of Health of the State of Pennsylvania in 1941. Suffice it to say here that great strides have been made in attempting to reduce the incidence of this disease in industry.

There is still not full agreement among authorities as to the treatment of choice in human anthrax. In 1941 Lucchesi and Gildersleeve³ in a report on the treatment of 67 patients at the Philadelphia Hospital for Contagious Diseases concluded that the administration of neoarsphenamine is the method of choice in most cases but that serum is the preferred agent when (1) the lesion is on the face or neck, (2) the blood stream has been invaded and (3) the patient has the "internal" type of anthrax. Furthermore, these authors felt that some patients with cutaneous anthrax "will get well without treatment if the lesion is left alone." Gold,⁴ reporting on the treatment of 60 cases of human anthrax, states that "sulfonamide compounds are a safe and reliable substitute for antianthrax serum" but presents several cases in which the sulfonamides appeared ineffective and serum was required for recovery. All authorities agree that attempts at destruction or removal of the lesion are fraught with grave danger and are strictly contraindicated.

From the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine and the Philadelphia Hospital for Contagious Diseases.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for experimental investigations recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council. The work was done under a contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development and the University of Pennsylvania. This paper was prepared for publication in March 1944 but not released by the Committee on Medical Research until September 26, 1944.

4. Gold, H. Anthrax: A Review of Sixty Cases with a Report on the Therapeutic Use of Sulfonamide Compounds. *Arch Int Med* 70: 780 (Nov.) 1942.

In his epoch making paper in 1929, announcing the discovery of penicillin, Dr. Alexander Fleming⁵ observed that the growth of *Bacillus anthracis* was inhibited in vitro by a penicillin concentration of 1/10. This compared with the inhibition of *Staphylococcus aureus* at a concentration of 1/400 and lack of inhibition of some gram negative bacilli at a concentration of 1/5. Abraham and his collaborators⁶ found that the growth of one strain of *B. anthracis* was inhibited in vitro at the same concentration as that which inhibited four different strains of *Staphylococcus aureus*. It seemed, therefore, that penicillin might be effective in the treatment of human anthrax. The 3 cases reported here are all of the nonbacteremic, cutaneous type and were proved bacteriologically. They were consecutive and unselected, and penicillin was the only specific medication administered.

REPORT OF CASES

CASE 1—History—S. G., a white woman aged 34, a wool worker, first noticed a whitish "pimple" on her left forearm on Oct. 29, 1943. The lesion increased in size, became painful and on November 1, the third day of the disease, she was admitted to the Philadelphia Hospital for Contagious Diseases. On admission the temperature was 99 F., the pulse rate was 102 and the patient appeared slightly toxic and anxious. The lesion, which was on the flexor surface of the left forearm 9 cm. from the wrist measured about 2 cm. in diameter and consisted of a central black eschar surrounded by a zone of small vesicles. Almost the entire flexor surface of the forearm from the wrist to the antecubital space was indurated and erythematous. The history and physical examination were otherwise noncontributory.

A continuous intravenous infusion containing penicillin was started on admission and continued for five hours, at which time, owing to technical difficulties, the infusion was stopped, so that the patient received approximately 25,000 units initially. Examination of the lesion at this time revealed that the area of erythema and induration about the lesion had almost completely disappeared. The intravenous infusion was then restarted and continued for twenty-four hours, during which time the patient received an additional 150,000 units of penicillin. The intramuscular route was then used and the patient received 12,500 units intramuscularly every two hours for forty-eight hours. The course of therapy lasted a little over three days and the patient received a total of 475,000 units of penicillin, of which 175,000 was given intravenously and 300,000 units intramuscularly.

The temperature remained normal after eighteen hours of therapy. The pain disappeared almost immediately and examination four days after admission showed that the erythema and induration had disappeared while the vesicles had become dry. The patient was discharged in good condition on the ninth hospital day.

Laboratory Studies—Blood examination revealed hemoglobin 12 to 13 Gm. and white blood cells 6,400 to 8,400, with 68 per cent neutrophils, 20 per cent lymphocytes and 11 per cent monocytes. Kolmer and Kahn tests were negative. Blood culture on admission was negative. Culture of the local lesion on admission and before penicillin was started was positive for *B. anthracis*. Cultures taken on the third, seventh and eighth days after admission were negative.

CASE 2—History—D. S., a Negro woman aged 18, a wool worker, was admitted to the Philadelphia Hospital for Contagious Diseases on Nov. 20, 1943, four days after she had

5. Fleming, A. The Antibacterial Action of Cultures of a Penicillium with Special Reference to Their Use in the Isolation of *B. Influenzae*. *Brit J Exper Path* 10: 226 (June) 1929.

6. Abraham, E. P., Chain, E., Fletcher, C. M., Gardner, A. C., Heatley, N. G., Jennings, M. A. and Florey, H. W. Further Observation on Penicillin. *Lancet* 2: 177 (Aug. 16) 1941.

first noticed a small papule on the left side of her face. This papule had increased in size so that on admission to the hospital examination revealed a circular lesion on the left side of the face above the zygoma measuring 2 cm in diameter. It consisted of a central black eschar covered with a serosanguineous discharge and surrounded by small clusters of vesicles. Just peripheral to the lesion was an area of erythema and induration measuring 2 cm in width. An enlarged and tender left preauricular lymph node was palpable. The temperature was 99.4 F. The history and physical examination were otherwise negative.

A continuous intravenous infusion of penicillin was begun, and during the first fifty-three hours the patient received 225,000 units in this manner. Then, because of the development of a mild thrombophlebitis, a change to the intramuscular route was made and the patient received injections of 8,333 units every two hours for twenty-four hours. The course of penicillin therapy lasted a little over three days and the patient received a total of 325,000 units, of which 225,000 units was given intravenously and 100,000 units intramuscularly.

Twelve hours after the onset of therapy the erythema was less, the serous discharge had disappeared, the vesicles had become dry and the preauricular lymph node was no longer tender. At the end of seventy-two hours of treatment all edema and erythema had disappeared, and the lesion was quite dry and appeared innocuous. The thrombophlebitis resulting from the intravenous infusion cleared up rapidly under conservative measures and the patient left the hospital on the ninth hospital day.

Laboratory Studies—Hemoglobin was 77 to 87 per cent, white blood cells numbered 11,900 to 8,200, with 63 per cent neutrophils, 35 per cent lymphocytes and 2 per cent monocytes. Kolmer and Kahn tests were negative. Blood culture on admission was negative. Smear and culture of the local lesion were positive for *B. anthracis* on admission (before the administration of penicillin) and on the day following admission (after about 50,000 units of penicillin had been administered). Cultures and smears taken on the second, third, fourth, eighth and ninth days after admission were negative.

CASE 3—History—L. D., a white woman aged 34, a wool worker, on Dec. 10, 1943 noticed a small 'pimple' on the ulnar aspect of her left forearm. On December 14 she received 0.3 cc of staphylococcus vaccine. A smear of the lesion made on the following day showed *B. anthracis*, and she was admitted to the Philadelphia Hospital for Contagious Diseases on December 15, five days after the onset of the disease.

Physical examination revealed a temperature of 99.8 F and a normal pulse, respiratory rate and blood pressure. On the ulnar aspect of her left forearm just above the wrist was a round, purplish red partially crusted, oozing lesion measuring 2 cm in diameter. Just peripheral to the lesion were a few clusters of vesicles, and the entire lesion was surrounded by a zone of erythema and induration. There was no adenopathy and the history and physical examination were otherwise negative.

A continuous intravenous infusion of penicillin was started and continued for forty-eight hours, so that she received a total of 100,000 units intravenously at the rate of 50,000 units per day.

After she had received about 40,000 units, examination revealed that the erythema and induration about the lesion had decreased considerably. After 100,000 units had been administered the lesion looked dry and the erythema had completely disappeared. The patient was discharged on the tenth hospital day.

Laboratory Studies—Hemoglobin was 80 per cent, white blood cells numbered 9,200 to 7,600, with 72 per cent neutrophils, 20 per cent lymphocytes and 8 per cent monocytes. Kolmer and Kahn tests were negative. Blood culture on admission was negative. Smear and culture of the local lesion on admission

were positive for *B. anthracis*. Smear and culture taken on the first and second days after admission were also positive. Smear taken on the third day, after the administration of 100,000 units of penicillin showed a few organisms but the culture was negative. The same was true on the fourth day. On the fifth, sixth, seventh, tenth and eleventh days after admission both smear and culture were negative.

COMMENT

The clinical response of these cases of anthrax to penicillin was rapid and definite. In each instance the inflammatory reaction about the lesion showed very prompt regression and the lesion itself underwent rapid involution.

The clinical response was paralleled by the disappearance of *B. anthracis* from the lesion. The organism in case 1 could not be seen or cultured after the administration of 475,000 units of penicillin. In case 2 culture and smear were positive after 50,000 units of penicillin had been given but were negative after the administration of 150,000 units. A small dosage of penicillin was deliberately given in case 3 and here

Comparative Susceptibility of *B. Anthracis* to Penicillin

it was seen that after 50,000 units culture and smear were still positive. After 100,000 units the smear remained positive but showed few organisms, and the culture was negative. Twenty-four hours after the administration of 100,000 units of penicillin the smear was still positive and culture was negative, but in forty-eight hours both smear and culture were negative. In none of the 3 cases did the organism reappear in smear or culture after its initial disappearance.

On the basis of these bacteriologic and clinical data it would seem that a total of 100,000 units of penicillin is certainly the minimum effective dose in the uncomplicated case of cutaneous anthrax. At least a total of 200,000 to 400,000 units of penicillin, given at the rate of 100,000 units in twenty-four hours, should be administered to the average adult, and this amount should effect a prompt and satisfactory therapeutic response. Continuous intravenous infusion is probably the most efficient route of administration, although intramuscular injections every two to three hours might be just as effective. No case of visceral anthrax or severe cutaneous anthrax with bacteremia has been treated with penicillin to our knowledge. In these cases larger doses should undoubtedly be administered by the intravenous route and perhaps serum should be given in addition.

The strain of *B anthracis* isolated in case 3 was tested in vitro for its sensitivity to penicillin by Miss Marjorie Wiley and was compared to *Staphylococcus aureus* and *Escherichia coli*. As may be seen in the table, the growth of *B anthracis* was completely inhibited by a concentration of 25 units of penicillin per cubic centimeter, the growth of *Staphylococcus aureus* was completely inhibited by a concentration of 0.025 unit per cubic centimeter, but the growth of *E coli* remained uninhibited in all concentrations. In other words, this strain of *B anthracis*, although sensitive to penicillin, was one hundred times less sensitive than *Staphylococcus aureus*. Fleming's strain¹ was forty times less sensitive than *Staphylococcus aureus*, while the organism of Abraham and his collaborators² appeared to possess the same sensitivity as *Staphylococcus aureus*. Allowing for possible differences in the resistance of the various strains of *Staphylococcus aureus* used in each study, it nevertheless appears likely that different strains of *B anthracis* may vary widely in their sensitivity to penicillin in vitro. This study also suggests that one must exercise some caution in predicting the clinical response of a disease to penicillin therapy on the basis of in vitro response of the etiologic agent to penicillin, for in this instance we have an example of a disease which shows pronounced clinical response to the administration of penicillin in small dosage and yet is caused by an organism which has been observed to possess a relatively low sensitivity to penicillin in vitro.

The place of penicillin in the therapy of anthrax and its relation to the other agents already used in this disease cannot be finally determined on the basis of 3 cases. Suffice it to say that penicillin is a chemotherapeutic agent of low toxicity which, in relatively small doses, appears to be remarkably effective in the treatment of cutaneous human anthrax. We believe that penicillin will acquire a prominent place in the treatment of this disease and that further clinical trial is warranted.

SUMMARY AND CONCLUSIONS

1 Three cases of uncomplicated cutaneous human anthrax without bacteremia were treated with penicillin. As far as we know, this is the first report on the use of penicillin in the treatment of patients with cutaneous anthrax.

2 Exceedingly prompt and excellent clinical response to penicillin was observed in every case.

3 Bacteriologic studies showed that there was rapid disappearance of *B anthracis* from the cutaneous lesions after administration of penicillin.

4 In vitro studies of the strain of *B anthracis* isolated in 1 case showed it to be sensitive to the action of penicillin, but one hundred times less sensitive than a strain of *Staphylococcus aureus*.

5 A total of 100,000 units of penicillin is certainly the minimum effective dose, and a total of 200,000 to 400,000 units, given at a rate of 100,000 units per day, should serve to evoke a satisfactory therapeutic response in the average uncomplicated case of cutaneous anthrax.

6 Penicillin is a valuable agent in the treatment of human anthrax and deserves further clinical trial in this disease.

THE ROENTGEN DIAGNOSIS OF TRAUMATIC LESIONS OF THE CERVICAL SPINE

MAJOR GILBERT W HEUBLEIN

Assistant Chief of X-Ray Section Percy Jones General Hospital
Battle Creek, Mich

MEDICAL CORPS, ARMY OF THE UNITED STATES

Twenty-five hundred years B. C. a certain author stated that "one having a crushed vertebra in his neck, he is unconscious of his two arms and his two legs and he is speechless." Thus, according to Stinchfield,¹ began the history of fractures of the spine. As recently as 1917 an eminent radiologist said "On account of the technical difficulties in making plates laterally, most of us have been content to make stereoscopic plates in the anteroposterior projection."² Present day technique of cervical spine radiography is not difficult, if done with care.

In Percy Jones General Hospital we have been fortunate in having one of the newer developments in

Fig 1—Conventional projections of cervical spine showing spina bifida occulta, calcified intervertebral disk and congenital fusion of second to third cervical and sixth to seventh cervical. Abnormal 8 shaped foramen at a normal for comparison at b. Note the narrow intervertebral disk between sixth and seventh cervical. This is a frequent finding in patients without symptoms. (Courtesy of Capt A. P. Dado.)

technical equipment—the Morgan meter.³ This is valuable in making both simple and difficult projections of the spine. The operation of the meter depends on the fact that intensity \times exposure time = a constant. Thus, if the intensity reaching the film is known in advance, the time for proper exposure can be determined algebraically. The Morgan meter does away with mathematical computations and the exposure time is read off directly from a calibrated scale on the meter. We have found the meter particularly valuable in taking various parts through casts and in other such cases where the examination for one reason or another may be considered technically difficult or where contrasty films are needed for any reason. With the aid of the Morgan meter excellent films of the cervical spine can be obtained through heavy plaster.

Read before the joint Section on Orthopedic Surgery and the Section on Radiology at the Ninety Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

In children one must bear in mind appearances mimicking fractures as a result of numerous ossification centers or areas of incomplete fusion⁴. In adults running vertically in the region of the dens, one encounters radiolucent lines due to the superimposed interproximal space of the central incisor teeth. Separate ossicles

Fig 2—Gunshot fracture of second and third cervical vertebrae. A 0.25 caliber Jap bullet struck this patient in the mandible and the missile lodged in the neck. Twenty four hours later he spat the bullet from his mouth. Note retrovisceral soft tissue swelling and bone spicules on the left. On right soft tissue swelling has returned to normal. Hypertrophic changes bridge the injured vertebral bodies. Very little ultimate disability resulted from this injury.

in the ligamentum nuchae may cause confusion, as will also the wedge shaped epiphysal deformity encountered with limbus vertebra. These are normal variants or at most the result of a disturbance of the ossification of the vertebral plates.

In addition to routine anteroposterior and lateral views made at 6 feet we often make films through the open mouth, oblique projections (50-55 degree rotation) and those in the Jackson position, which

Fig 3—P. C. S., a private first class aged 21, was injured when thrown from a truck. Films showed fracture through the base of the odontoid with posterior displacement. Following head traction the deformity was completely corrected.

is similar to an exaggerated Waters view used in paranasal sinus examinations. It should be emphasized that the transoral view is essential in every case of neck injury. The less well known Jackson view is often helpful. The oblique views, as in figure 1, show the interver-

tebral foramina to best advantage. In certain instances fracture lines can be detected only in such projections. A normal intervertebral foramen has a smooth, oval appearance, while one with hypertrophic changes along its margins has an 8 shaped outline due to projecting osteophytes in its midportion. Hypertrophic changes may be of importance as a cause of symptoms and if located at or above the fourth cervical vertebral level may give rise to the swollen atrophic hand⁵ without local cervical spine symptoms. Often numerous views are required before fractures in hypertrophic spurs can be demonstrated⁶.

Fractures of the cervical spine comprise 23 per cent of the cases of vertebral fractures examined in our department. They can be divided into two categories: 1. Those which affect the cord protecting portion of the spine, i.e., the neural arch and its processes. 2. Those which affect the weight bearing structures of the spine, i.e., the vertebral bodies. Vertebral body fractures may vary from minute spicules projecting

Fig 4—Transoral films showed the fracture line well visualized one month after the accident (see right hand illustration). This is due to presence of a rarefying osteitis.

anteriorly or a moderate bulge along the anterosuperior margin of the body to considerable compression of the spongy portion, with or without detached fragments. In the cervical spine—a relatively unprotected portion of the vertebral column—dislocations are often present and may or may not be associated with fracture. In sharp contradistinction is the dorsolumbar region, where dislocations are almost invariably associated with fracture. The soft tissues adjacent to the vertebral bodies must be carefully inspected. Any swelling of these structures indicates the presence of hemorrhage, edema or infection. In fractures of the arches, callus formation may be a prominent feature⁴.

The following case illustrates a compression fracture due to gunshot wound.

A private aged 23 was wounded by a sniper in New Guinea in December 1942. He crawled to a first aid station and twenty-four hours after the injury he spat a 0.25 caliber bullet out of his mouth. A comminuted compression fracture associated with pronounced swelling of the retropharyngeal structures

resulting from hematoma was seen. A year later the fracture was well healed and bridged by osteophytes. On physical examination minimal disability in flexion and extension was observed (fig 2). Fortunately this patient escaped osteomyelitis, a not infrequent complication of gunshot wound in this area.

Fig 5—Abnormal distance between the lateral masses of the first cervical vertebra and the dens. This space should ordinarily not exceed one half the transverse diameter of the odontoid process.

An important consideration in examining the cervical spine is the use of the films made in the lateral direction with the neck in flexion and extension. This has been known for many years, but its importance should not be overlooked. Exposures made in flexion may show a subluxation not demonstrable in conventional views.

The first and second cervical segments represent a very special area. Fractures through the base of the odontoid process may not be shown at the initial examination and may be revealed only some weeks later, when additional studies indicate the presence of a rarefying osteitis along the fracture line. Delayed films may be necessary before proper diagnosis is made. The patient should not be accused of malingering on the

Fig 6—While walking in North Africa a private aged 24 was struck by a car. He was unconscious for six hours. A special film in the Jackson position showed a chip fracture of the odontoid at *a* and a fracture of the arch of the atlas at *b*. Same case as figure 5.

basis of a single early negative examination. Fractures here may give rise to symptoms simulating those produced by the cord changes of primary pernicious anemia.

7. Pendergraft, E. P. Personal communication to the author. Wat on Jones, R. Fractures and Other Bone and Joint Injuries. Edinburgh: E & S Livingstone, 1940.

The roentgenologist must be conservative in interpreting films of this region, taking care to recognize definite abnormalities and by the same token avoiding false positive diagnoses. In the next case (figs 3 and 4) there was a fracture of the dens with posterior luxation adequately corrected by head traction after six days. Seven months after injury the fracture line was still well shown because of a rarefying osteitis along the fracture cleft. These lesions usually heal by fibrous union. Isolated fractures of the atlas are relatively rare, only 99 having been reported since 1822.⁸ The bilaterally symmetrical wide separation of the lateral masses of the atlas seen in figure 5 might be easily overlooked. The space normally present on each side of the dens does not ordinarily exceed one-half the transverse diameter of the odontoid process. In this particular individual, by means of the Jackson position shown in figure 6, we were able to identify two definite abnormalities in the region of the atlanto-odontoid joint. These included a chip fracture lateral to the dens and definite evidence of fracture in the posterior arch of the atlas. This

Fig 7—Two types of vertebral fracture: that of the posterior processes shown at *a* and crush fracture of the twelfth dorsal vertebral body at *b*.

patient made a satisfactory recovery and was returned to duty.

Recently Nachlas⁹ suggested that arm pain of parachute jumpers may be attributed to the whiplash effect of the sudden opening of the parachute, particularly when the soldier holds his neck in an awkward position. In a review of 57 cases in the Royal Air Force, Hall and Morley¹⁰ make the following significant statement: "Aircraft accidents may on occasion be appallingly destructive in their effects, yet it is surprising how much the human frame can tolerate and how often the pilots and co-pilots are uninjured when the machine may be totally wrecked. Conversely, slight accidents may have tragic results through sheer misfortune." Only 1 case of cervical spine fracture resulting from a flying accident is reported by them. Cervical spine fractures in parachutists are much less common than one might expect—approximately 2 in 10,000 jumps.¹¹

The following case illustrates both categories of spinal fractures (injury of the posterior processes plus crush

fracture of the centrum), showing a break through the seventh cervical spinous process and a crush fracture at the dorsolumbar junction (fig 7)

A staff sergeant was flying over New Georgia, when his plane was forced down by Japs. He parachuted to earth with his co pilot, who had a broken arm due to gunshot wound

Fig 8—Roentgen anatomy of the Jackson position showing the appearance of a proved case of rotary dislocation. Dotted lines indicate the approximate normal position of the transverse processes prior to dislocation

They landed in enemy territory and heard Japs all around them but managed to crawl 500 yards through the jungle to the ocean and started swimming. The sergeant's abdomen became greatly distended because of ileus and both men were in a critical condition. They were rescued by friendly natives, who took them by canoe to a nearby island. Here they were able to communicate by radio with an army base and were picked up by a flying boat. Four weeks later the patient was receiving treatment in our hospital. This type of cervical spine fracture requires no surgical intervention. The dispatch with which this soldier was transferred to the zone of the interior needs no comment.

Fig 9—Position employed for cone down study of cervicodorsal junction. Pointer at a showing position of central ray is directed to the base of the cervical spine. For the left lateral projection as indicated here the left hand is placed on the head and the right shoulder is depressed. A satisfactory average technic with rotax tube is 60 70 80 kilovolt peak 100 milliamperes (one second at 100 milliamperes) medium sized telescopic cone. Bucks focal distance 36 inches.

Another cervical spine lesion of importance is that of rotary dislocation of the atlas (fig 8). This may be aggravated by trauma but often is the result of upper respiratory tract infection, especially when a cervical lymphadenitis is present. It is stated also to occur

as a result of muscle spasm in poliomyelitis or when there is congenital absence of the dens or asymmetrical development of facets.¹² An illustrative case follows.

A private aged 23 who had two previous episodes of neck trauma had a tonsillectomy in February 1943. One week later he was returned to duty. In the latter part of March he complained of stiffness of the neck. Physical examination showed muscle spasm and enlarged cervical lymph nodes. A pronounced torticollis was present. Our x-rays showed a rotary dislocation of the axis on the atlas. Traction was employed, and in four days the muscle spasm subsided. Examination then showed the displacement corrected. While in traction he had radiculitis in the left arm and pain radiating to the front of the chest. A pantopaque myelogram failed to reveal evidence of a ruptured disk. In November the patient was up and comfortable but considerable restriction of the motion of the neck was still present and roentgen examination showed some narrowing of the atlantoaxial joint.

Pathologic fractures of the cervical spine are of interest because of their rarity and must be differentiated from those caused by trauma.

A white man aged 56 complained of minimal pain at the base of his neck following a cystoscopy. The cervicothoracic junction was somewhat prominent. No point tenderness was noted.

Fig 10—Film on left shows metal brace obscuring the odontoid. Film on right shows complete obliteration of brace as the result of laminographic study—section made at level of external auditory meatuses. There is an alteration in the normal contour of the dens due to fracture. (Courtesy High M. Wilson, MD.)

Twenty-three days after cystoscopy a narrowed interspace was seen in the cervical spine films and the patient had an alternating low grade temperature with increasing pain in the distal cervical region. Special films were secured employing the technic shown in figure 9. These demonstrated a definite dislocation of the facets of the sixth and seventh cervical vertebrae. Films made after traction showed the segments in normal position with slight residual compression of the seventh cervical. These changes were felt to be the result of an osteomyelitis.

This case is included to stress the difficulties faced by the radiologist unless an adequate clinical history is available. The lower cervical segments are often difficult to visualize in short necked patients with heavy shoulders.

In certain instances the planigraph, or laminagraph, is of definite value. No dogmatic stand can be taken regarding such examinations, so much depends on the type of conventional films secured and their interpretation. The laminagraph is of importance in obliterating the shadow of metal braces or other orthopedic paraphernalia which in conventional films may obscure the anatomic detail.^{12a}

In cases of pain referable to the cervical spine the diagnosis of a ruptured nucleus pulposus must be con-

12 Nicholson J. T. Spontaneous Reduction of Cervical Spine Dislocations. J. A. M. A. 115: 2063-2069 (Dec. 14) 1940.
12a Wilson H. M. Personal communication to author.

sidered The intervertebral disk buffer may be disturbed by minimal traumas often repeated or by a single severe injury Myelograms are done in our hospital in some such cases, Pantopaque (ethyl iodophenylundecylate) being the contrast medium used The case illustrated in figure 11 presented a large filling defect at the level of the sixth cervical vertebra This was proved at operation to be due to a herniated nucleus pulposus

Experience with myelography indicates that successful delineation of such lesions is not always easy Accurate diagnosis is dependent on several important factors

1 Proper apparatus, including the use of a canvas support and a special attachment for obtaining lateral films in the prone decubitus

2 Adequate extension of the neck to prevent the escape of the opaque material into the basal cisterns¹³

3 Accurate spinal puncture by a neurosurgeon experienced in this type of procedure This cannot be too strongly emphasized

Fig. 11—Defect produced by a large ruptured disk is shown on the right. Pain in shoulder and neck radiating down into first three fingers was made worse by coughing and straining. Minimal herniation is shown at left. Such a lesion could not be diagnosed without the aid of multiple films and close correlation of all the clinical findings. A small laterally placed disk was removed between the sixth and seventh cervical vertebrae with complete relief of symptoms. (Courtesy of R. Glen Spurling lieutenant colonel M. C. and Benjamin B. Whitcomb captain M. C.)

4 Proper withdrawal of the opaque medium at the completion of the examination to be checked by a scout film of the area examined¹⁴

5 Lastly, and perhaps of most importance, the close correlation of clinical and radiographic findings

CONCLUSIONS

1 The cervical spine, as the result of its relative lack of protection, is subject to many different types of injury

2 The roentgen examination is an invaluable aid in diagnosis and differential diagnosis

3 A thorough knowledge of the anatomy plus the roentgen technic indicated in the demonstration of various lesions is essential if the accurate diagnosis is to be attained

POLYCYTHEMIA VERA

FINAL REPORT ON A CASE UNDER CONTINUAL TREATMENT WITH PHENYLHYDRAZINE HYDROCHLORIDE FOR ELEVEN YEARS

CLAIR L. STEALY, M.D.

AND

HAROLD S. SUMERLIN, M.D.

SAN DIEGO, CALIF.

This is a final report on a case of polycythemia vera which was under observation for seventeen years, and for eleven of these years under continual treatment with phenylhydrazine hydrochloride. It is presented (1) because of the long period of treatment with the drug, (2) to record the changed blood picture during the last six years of life and (3) to report the autopsy findings.

Until a year before the patient died at the age of 72 years she led a useful and normal life. For the first eleven of the seventeen years the patient was under our observation the disease was successfully controlled, from the standpoint of the blood picture and subjective symptoms, by phenylhydrazine hydrochloride. Then, six years before death, a leukemoid type of blood picture developed. Three years before the change in the blood picture occurred a carcinoma of the cervix had developed which was effectively treated with radium. The radium had only temporary, if any, effect on the blood picture. The physical findings remained much the same as at the time of our last report in 1932.¹ In appearance the patient had aged. Her color, even up to the time of her death, would have led a trained observer to suspect the presence of polycythemia vera. The heart apparently became somewhat enlarged and there was evidence of mild myocardial and vascular degeneration, the blood pressure remained within normal limits. There was slight enlargement of the liver but no more than would be expected with the heart and circulatory changes or with an enlarged spleen. The spleen extended to the midline and almost to the crest of the ilium but this represented no appreciable change in size since the patient was first seen in 1924. The kidney function as determined by the phenolsulfonphthalein test and the liver function as determined by the hippuric acid test were normal in 1938, as were the icterus index and the van den Bergh reaction. Analysis of the gastric contents after the Ewald meal revealed an absence of free hydrochloric acid and a total acid content of 9 degrees. During the last few months of life an edema and an abdominal ascites which required removal of fluid by paracentesis at frequent intervals developed.

The blood picture began to change in 1935 after eleven years of treatment with phenylhydrazine hydrochloride. With the red cells numbering about 7 million the patient started her medication as usual. This time the number of red blood cells dropped from 7 million to 4 million, a slightly greater response to the drug than had been normal for her. Then, instead of the usual gradual increase in red cells with the withdrawal of the drug, there was a continued decrease to between 2 and 3 million, at which level they remained for the remaining six years of the patient's life. The hemoglobin concentration of the blood, which had varied from 12 to 17 Gm per hundred cubic centimeters, fell in like

1 Stealy C. L. Polycythemia Vera. Report of Case Treated with Phenylhydrazine Hydrochloride over Period of Seven and One Half Years. *J. A. M. A.* 98: 1714-1716 (May 14) 1932.

manner to a level of 7 to 9 Gm per hundred cubic centimeters. The presence of normoblasts was noted and poikilocytosis, polychromatophilia and achromia appeared. The leukocyte count, which had previously maintained a high level of 15,000 to 20,000 with occasional jumps to 25,000 and 30,000, dropped with the red cell count and during the last five years ranged between 5,000 and 10,000 with an occasional rise to 12,000 or 13,000. The first myelocytes appeared in the blood smear at sporadic intervals two years before the red cell count dropped and became a constant finding during the last six months of phenylhydrazine therapy. The possibility of the development of a primary anemia was considered in view of the lack of gastric acid even though the blood picture was not typical, but there was no reticulocyte response to liver therapy. It has been observed by others that the gastric acid falls with increasing polycythemia² but that the antianemic principle of Castle which is absent in pernicious anemia is present in excessive amounts in polycythemia vera.³

The blood picture suggested the development of a leukemia, but microscopic examination of the blood smear did not bear out such a diagnosis. Dr. Charles A. Doan of the Department of Medicine at the Ohio State University College of Medicine, who examined some of the blood films wrote

I was particularly impressed by the changes in the red blood cells. There was marked variation in size and shape of the erythrocytes, and a definite polychromatophilia and achromia. There was an unusual number of red cells showing punctate basophilia, sometimes 2 or 3 being seen in a single oil immersion field. There were many microcytes and occasional macrocytes. The average diameter as revealed by the Eve halometer was 7.64 microns. The blood platelets were, for the most part, sparsely scattered as single units and varied strikingly in individual size, there being microthrombocytes as well as macrothrombocytes. As far as the white cells are concerned, I should feel that the findings were indicative of a definite myeloid hyperplasia of the marrow, primarily of the neutrophilic granulocytes. The percentage of myeloid elements together with the very definite "left shift" principally to the band form stage, with only 6 per cent actual myelocytes present, and no increase in basophils or eosinophils, does not bespeak an active leukemic process. Furthermore, the quality of the myelocytes is not suggestive of a leukemic anaplasia. The lymphocytes show a moderate degree of "left shift" not pathognomonic. The presence of an occasional nucleated red cell, the very marked polychromatophilia, and especially the degree of punctate basophilia, when coupled with marked size and shape changes, and 12 per cent of toxic granule neutrophils among the white cells, could only be interpreted as a reflection of a toxic hemolytic destructive agent.

A year later blood films were again sent to Dr. Doan. He saw no change in the general hematologic picture and interpreted the findings as "representing very active myeloid and erythroid activity in the bone marrow under some disadvantages, toxic or otherwise, together with an accompanying disturbance in the normal function of the megakaryocytes, that is to say, an abnormality which affects all of the active hemopoietic elements in the bone marrow."

There was little change in the blood picture from this time until the death of the patient in 1941. The following is a representative blood count of this period: hemoglobin concentration of the blood 9 Gm per hundred

cubic centimeters, erythrocytes 2,900,000 and leukocytes 7,800. The leukocytes were differentiated as follows: neutrophils 80 per cent, of which 53 per cent were band forms, 25 per cent segmented forms and 6 per cent myelocytes, lymphocytes 14 per cent, eosinophils 1 per cent, and basophils 1 per cent. There was 1 normoblast to every 100 erythrocytes.

The necropsy report is given in its entirety.

The arterially embalmed body was that of a quite emaciated white woman, 67 inches (170 cm) long and weighing about 90 pounds (41 Kg). The abdomen was distended and showed an old low midline scar. There was moderate edema of the feet and legs. The superficial lymph nodes were not enlarged. The tissues gave the appearance of anemia.

The brain showed moderate atrophy of the convolutions with widening of the sulci but otherwise was normal. The meninges appeared normal. The arteries were moderately sclerotic. The pituitary gland appeared normal.

There was a small amount of clear fluid in both pleural cavities. The lungs showed only hypostatic congestion. The heart was normal in size. The epicardium showed an area of edema at the apex but otherwise the heart was normal. The aorta was moderately sclerotic. The mediastinal lymph nodes were not enlarged.

The abdominal distention was due to a large quantity of clear yellow fluid. The mesenteric, gastric, splenic and esophageal veins were greatly enlarged. A segment of small intestine was adherent to the old scar. The peritoneum was smooth but somewhat opaque. The spleen extended to the brim of the pelvis (1,950 Gm, 25 by 5 by 10 cm). The surface was rough and dull gray with several yellow patches (2 to 5 cm) which were the sites of infarcts. The consistency was firm and fibrous. The cut surface was dull brown with white fibrous bands. The capsule was 2 mm thick. The liver was somewhat enlarged (1,820 Gm) and firm, and the edge was rounded. The surface of the right lobe was fairly smooth. A great part of the left lobe showed a nodular surface. It cut with increased resistance, the cut surface being pale in appearance and homogeneous. The capsule was thickened. The gastrointestinal tract and pancreas appeared normal. The surfaces of the kidneys were granular, the capsules adherent. On the cut surfaces the markings were distinct, but the cortex was reduced in thickness. The adrenals appeared normal. The bladder and ureters were normal. The uterus, tubes and ovaries had been surgically removed in the distant past. The mucosa over the vault of the vagina was smooth. There was a fibrous nodule which was regarded as the remnant of the cervix uteri, the os having been destroyed by radium treatment.

There were no enlarged pelvic lymph nodes. The aortic chain of nodes and the hilar nodes of the spleen were quite large (25 by 15 by 1 cm), firm and of fibrous consistency. Those about the spleen were brownish red (pigment). The marrow in the middle third of the tibia and femur was deep red and quite firm. The vertebral marrow was similar in appearance.

On microscopic examination, the spleen showed marked fibrosis. The follicles were widely separated. Myeloid cells, including an occasional megakaryocyte, were present but not in large numbers. There was a considerable quantity of phagocytized pigment. The lymph nodes were quite fibrotic, with thickened capsules. The lymphoid tissue appeared as islands separated by fibrous bands. The germinal centers were small and inconspicuous. There were myeloid cells including an occasional megakaryocyte scattered through the sections. There was considerable phagocytized pigment. This was quite extensive in the splenic nodes. The reticulum was not increased.

The bone marrow presented the picture of myelosclerosis with fibrosis and vascularization. It was relatively deficient in hemopoiesis except for megakaryocytes of all sizes, which were present in great excess. Phagocytic cells with ingested pigment were fairly numerous. The marrow was engorged with erythrocytes.

Periportal fibrosis in the liver varied in intensity in different areas. It was most marked in the left lobe. There was atrophy of the liver cells and many areas of fatty degeneration. Small

2 Apperly, F. L., and Cary, M. Katherine. The Relation of Gastric Acidity to the Erythrocyte Content of the Blood. *Am J Digest Dis* 3: 466, 1935.

3 Adamson, W. B., and Storey, J. E. Observations on Etiology of Polycythemia Vera. *Texas State J Med* 36: 26-29, 1940.

infiltrations of myeloid cells and lymphocytes were most prominent beneath the thickened capsule

Numerous sections through the stump of the cervix showed nothing to indicate a previous malignancy. The kidneys, pancreas, adrenals, heart, lungs, brain and hypophysis showed nothing noteworthy. The infiltrations of myeloid cells in the spleen, liver and lymph nodes were regarded as being not extensive enough to suggest a leukemic process. No sections showed anything suggestive of metastatic carcinoma.

Summary: cirrhosis of the liver with ascites, splenomegaly with fibrosis and infarction, myelosclerosis, lymphadenopathy, myeloid infiltrations in liver, spleen and lymph nodes, healed carcinoma of cervix uteri.

COMMENT

After eight years of treatment with phenylhydrazine hydrochloride in this case, we concluded¹ (1) that, once the necessary dosage was established for an individual patient, the patient would respond to that dosage consistently, (2) that the patient does not acquire a tolerance to the drug and (3) that the drug apparently produces no deleterious effect on the liver and kidneys. Observation of the patient for the remaining nine years of her life, during the first three of which treatment with phenylhydrazine hydrochloride was continued, did not change the first two of these conclusions. The final outcome of the case and the necropsy findings make it impossible to say conclusively that the drug had no deleterious effect on the liver. However, neither can we hold the drug responsible for the cirrhosis which finally developed, for serious liver damage is known to occur in cases of polycythemia in which the drug has not been used. We can only state that after eleven years of treatment with phenylhydrazine hydrochloride no evidence of liver damage, aside from palpable enlargement of the liver, which is a frequent accompaniment of an enlarged spleen, could be demonstrated. Changes in the hemopoietic system such as those which took place in this case have been reported also in cases not treated with phenylhydrazine, so that these cannot be considered effects of the drug. From our observation of this case, in the light of our present knowledge of the disease and its control, we feel that, in the absence of the usual contraindications to the use of the drug, phenylhydrazine hydrochloride offers a satisfactory form of treatment for polycythemia vera.

The possible relationship between polycythemia and leukemic processes, their concurrent presence in the same patient and the apparent shift from one to the other in some cases have been discussed in many excellent articles. The necropsy findings in our case, both on macroscopic and on microscopic examination, were no more diagnostic of a myelogenous leukemia than were the changes in the blood picture. We can describe them only as leukemoid rather than leukemic in character. Dr. Doan, whose interpretation of the blood films in the case we have already quoted, and Dr. Roy R. Kracke of Emory University reviewed these sections. Both concurred with our conclusions. Dr. Doan wrote "I certainly can find no evidence in any organs studied or in sections available of anything that would lead me to make a diagnosis of myelogenous leukemia." In commenting on the bone marrow he said "I had rather the impression of exhausted or 'burned out' or toxically inhibited myelopoietic activity in the marrow." Dr. Kracke's impression was "that this was a case of polycythemia vera of years' standing which terminated with a leukemoid reaction and anemia."

Based on a review of 163 cases of polycythemia vera, Tinney, Hall and Giffin⁴ felt that the degree of splenomegaly and the presence of a leukemoid reaction were directly correlated with the duration of the polycythemia, although they did not consider their data in this series sufficient to prove this. We are inclined to believe that the change in the blood picture of our patient represents the usual outcome of all cases of polycythemia vera of sufficient duration. The true nature of the underlying process remains to be determined.

PRACTICAL CONSIDERATIONS

A case of polycythemia vera was under observation for seventeen years. For the first eleven years of this period, until a definite change in the blood picture occurred, the disease was apparently controlled by phenylhydrazine hydrochloride. The extensive liver damage which was found at autopsy six years later was not evidenced until the last year of life. Since both hemopoietic changes and liver damage have been reported in cases not treated with phenylhydrazine hydrochloride, the possibility of the development of these conditions would not appear to be a contraindication to the use of the drug. The changes in the blood picture, which may constitute a part of the disease process in cases of sufficient duration, are not clearly understood at the present time.

Clinical Notes, Suggestions and New Instruments

ACUTE EPIDURAL ABSCESS OF THE SPINAL CANAL

COMPLETE RECOVERY FOLLOWING EMERGENCY LAMINECTOMY AND PENICILLIN

EARL R. DONATHAN, M.D., KNOXVILLE, TENN.

Death from acute epidural abscess of the spinal canal is needless. It is important, however, that an early diagnosis of the abscess be made and decompressive laminectomy effected. This obviates the pressure which produces in the lumbar region, if unrelieved, rapid paralysis of the legs and urinary bladder. If many hours are lost after paralysis and anesthesia of the legs have become complete, permanent paraplegia, if not death results.

An observing doctor will seldom miss an epidural spinal abscess. The patient, recovering from multiple boils, begins to have an unexplained fever. There next develops a severe pain in the back. If a blood count is made, a pronounced leukocytosis is present. The fever continues and soon there is tenderness over the spine. Urinary retention ensues and there develops a complete paraplegia with loss of all sensation below the level of the lesion. All these signs and symptoms have occurred within forty-eight hours of the onset of pain in the back.

Surgical intervention must now be employed, else the patient dies from an extending infection, i.e., pyemia or ascending pyelonephritis. At this stage, spinal puncture can verify the presence of an abscess of the spinal canal. A very cautious tap, however, is necessary with repeated removal of the obturator and aspirating as the needle advances. If pus is encountered the needle is withdrawn and steps for an immediate laminectomy are taken. If the site where the puncture is made is free of pus, the needle can be advanced into the subarachnoid space. The demonstration of a spinal fluid block is indicative of an

From the Division of Neurosurgery, University of Tennessee School of Medicine and the Fort Sanders Hospital Surgical Service at Fort Sanders Hospital.

extradural abscess and not an infection of the cord, per se. The pus and granulation tissue removed, plus the decompressive measures afforded by laminectomy, relieve the pressure on the cord and help the circulation to reestablish itself.

The incidence of the epidural spinal abscess is unknown. In 1926 Dandy¹ stated that he had had no patients with an epidural abscess nor had he seen the condition at necropsy. He found, after reviewing the literature, 25 cases which had occurred and been reported. Many more cases have been reported since Dandy made his survey and made his worthwhile contribution to knowledge of the anatomy of the epidural space.

ANATOMY

The epidural space is dorsal to the spinal roots, there exists no space ventrally as the dura is firmly adherent to the vertebrae in this location. Only a potential space exists in the cervical region. From the seventh thoracic to the second sacral vertebrae, where the space ends, the size is variable, being widest in the midthoracic and midlumbar region. These anatomic facts are cited to explain the frequency with which inflammatory processes localize in either the midthoracic or the midlumbar region. Fat, areola tissue and blood vessels fill the epidural space.

ETIOLOGY

The majority of abscesses arise by metastasis from furuncles of the skin via the blood stream. It is possible, however, for them to occur by direct extension from suppurating lesions in the adjacent tissue. While boils are the most common etiologic factor, as reported by Gasul and Jaffe² the source of the organism was unknown in 179 per cent of these cases, but there was history of trauma.

The staphylococcus is the organism that is responsible in the majority of cases; however, Delearde³ reported a case caused by the streptococcus and Schick⁴ reports 1 caused by the pneumococcus.

DIAGNOSIS

An epidural abscess of the spinal canal should be suspected when a patient with furuncles or a history of trauma begins to show an elevated temperature and have root pains in the back and weakness of the legs. Weakness of the legs alone forces us to rule out tumors of the canal with compression of the cord. Pott's disease must also be considered. All these conditions are afebrile. If, on the other hand, elevated temperature exists and epidural abscess is ruled out, then one considers infectious myelitis and poliomyelitis. To rule out the latter two conditions in which no block exists a Queckenstedt test is done using the simple manometer which measures pressure in millimeters of water.

To determine the level at which to operate one depends on tenderness of the spine on palpation and establishment of a definite sensory level by careful neurologic examination. In epidural abscesses of the cord a lumbar tap is not without danger. The cautions just mentioned should be rigidly adhered to else there is the possibility of the point of the needle being carried into the subarachnoid space with resultant meningitis.

TREATMENT

No time is left for procrastination, once diagnosis of an epidural abscess with compression of the cord is made. Since destruction of the spinal cord is out of proportion to the amount of compression, the laminectomy is extended in both directions until the lesion is exposed in its entirety. When the upper limit of the pathologic area has been reached and the area is cleared of pus and granulation tissue, the cord will begin to pulsate. The dura is not opened. After removal of as much of the granulation tissue and pus as possible has been accomplished, adequate drainage of the epidural space is assured

by placing a small penrose drain on the surface of the dura. The wound is frosted with sulfathiazole powder and closed loosely, thus encouraging granulation from the bottom. I feel that when the causative organism is the staphylococcus, the streptococcus or the pneumococcus, as determined by direct smear, penicillin is of prime importance and should be started immediately.

PROGNOSIS

Cases in which recovery occurs without the benefit of surgery are the exception and very rare. When surgical intervention has been carried out before the paralysis has been complete for more than a few hours, there is a chance for some recovery. In 60 cases of Abrahamson,⁵ survival occurred in 20 of the 30 cases in which operation was performed. Of the 30 patients not operated on, none survived. If operation is delayed until paralysis has been complete for a number of days, Echols⁶ states that operation is usually contraindicated.

Patients operated on after paralysis has been complete for as long as twelve hours usually recover enough to walk and control the sphincters, yet usually retain residual motor disturbances.

REPORT OF CASE

M. W., a white girl aged 12 years, was admitted to Fort Sanders Hospital in Knoxville, Tenn., June 6, 1944 complaining of pain in the lower part of the back radiating into the chest. About three weeks before, the patient had a severe blow to her buttocks, the result of a fall from a teeter board. One week before entering the hospital she was confined to bed because of pain in the buttocks. A few days later the pain was in the lower part of the back and was very severe. The night before admission to the hospital the patient was still ambulatory, but there was a noticeable foot drop and walking was difficult. It was necessary to catheterize her to obtain a specimen of urine, as she was unable to void spontaneously. Eight hours after admission to the hospital the child had developed a complete paraplegia and a paralyzed bladder. A neurologic consultation was then requested.

Examination divulged an oral temperature of 103 F., nuchal stiffness, abdominal distention and tenderness, flaccid paralysis of the lower extremities and anesthesia downward from the level of the inguinal ligament bilaterally, with pronounced tenderness over the twelfth thoracic and first and second lumbar spinous processes. A cautious lumbar puncture was done with negative pressure being maintained by using a 2 cc Luer syringe attached to the spinal needle. When thick pus was aspirated extradurally, the needle was immediately withdrawn.

Three hours later, under general anesthesia, the spines and laminae of the eleventh and twelfth thoracic and first, second and third lumbar vertebrae were removed. As soon as the ligamentum flavum was incised, pus welled up into the wound. The area exposed was cleaned of granulation tissue and pus at the end of this procedure the cord was pulsating nicely. A rubber tissue drain was placed in the wound and on the dura, the operative site sprinkled with sulfathiazole and closed loosely. Four hundred thousand units of penicillin was given intramuscularly, 12,500 units every three hours until the temperature was normal for a period of twenty-four hours.

On the eleventh postoperative day, the patient was able to move the toes of both feet and could discern a pinprick to just below the knee bilaterally. On removal of the indwelling catheter the patient was able to void after being given an ampule of a preparation of carbaminoylecholine chloride. Three days later urination was normal. Twenty days postoperatively, sensation was normal in both legs and there remained only slight muscular weakness of the lower limbs. By the twenty-fifth postoperative day the wound had healed by secondary intention and the child was dismissed from the hospital. The patient was seen on the thirty-first postoperative day and no muscular weakness remained. Sensation was normal in both legs in their entirety.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT OF THE COUNCIL

The Council has authorized publication of the following report. The outline in this report is offered as an objective, a pattern and not a regulation. However, it has been adopted for publication with the belief that it will be of help to manufacturers and scientists who undertake the investigation of new drugs.

AUSTIN SMITH, M D

Secretary of the Council on Pharmacy and Chemistry
CHICAGO

A new drug should pass through several phases of investigation before it is declared suitable for distribution in commerce. It should be studied in the laboratory and in the clinic, the details of the study depending on the nature of the ingredients and the intended uses, but all investigations should follow a general plan which will permit a thorough understanding of the usefulness and toxic properties of the drug.

In considering new drug applications in the enforcement of the Federal Food, Drug and Cosmetic Act, the Food and Drug Administration is concerned primarily with evidence of safety. The Council on Pharmacy and Chemistry is concerned not only with the evidence of safety but also the evidence adduced to support the claims made for new drugs. Too frequently this evidence is found inadequate and the sponsors of new preparations, if they wish to provide the missing data, may find it necessary to repeat some of the more time consuming and expensive procedures and at other times find it advantageous to proceed along entirely new lines of thought. If the manufacturer has adequate facilities for laboratory and clinical appraisal, he can usually obtain the desired information within a reasonable period. Frequently however such facilities are not immediately available and much effort must be spent in searching for appropriate channels for investigation. If a comprehensive outline had first been prepared and then closely followed, loss of time and expenditure of needless effort might have been avoided.

At the same time it is an advantage for physicians and allied scientists to know by what standards a new drug has been evaluated. When the physician is urged to use this agent, he should have available such evidence as will satisfy his questions concerning safety and efficacy.

The activities of the Council on Pharmacy and Chemistry of the American Medical Association in this

field have recently been described.¹ Certain phases of the activities of the Food and Drug Administration which bear on this problem have also been published or are in press.²

The Council on Pharmacy and Chemistry has provided for almost forty years a set of rules to guide manufacturers for the submission of articles for inclusion in New and Nonofficial Remedies. At periodic intervals it has enlarged on these rules to provide criteria such as those found acceptable for the evaluation of skin disinfectants and contraceptives.³ Usually the criteria have been concerned with one special agent or class of agents. The Federal Food, Drug and Cosmetic Act provides that applications for new drugs shall contain "full reports of investigations which have been made to show whether or not such drug is safe for use," and the Food and Drug Administration provides a form in which are set forth suggestions concerning the scope and character of these reports.

If the utmost of possible benefits with a minimum of possible dangers is to result when a new drug is introduced for experimental trial and later in commerce, it is necessary to develop methods of appraising the therapeutic usefulness and potential harmfulness of new drugs and to organize these methods into a logical system which, if followed, will give reasonable assurance that the new preparation will not be offered to the medical profession or to the public before the extent of its usefulness or the potentialities for harm are understood. The present paper outlines the principles which have been helpful in making such an appraisal of new drugs.

PRELIMINARY OBSERVATIONS

The preliminary experimental observations with a new agent give the clue to the possible field of usefulness. In dealing with chemotherapeutic agents, these preliminary observations consist usually of tests of the efficacy of the agent in combating or preventing some experimental infections. In the case of drugs that might be termed "symptomatic agents," the preliminary observations should include tests of the possible pharmacodynamic actions of the drug. These observations "set the sights," so to speak, and indicate the course to be pursued in subsequent and more detailed investigations.

LABORATORY OBSERVATIONS

Assuming that a new drug has shown promise in the preliminary tests, more extensive inquiry must now be made into the mechanisms of its action and its

The authors wish to express their appreciation of the helpful comments offered by Dr. Torald Sollmann, Dr. P. J. Hanzlik, and Dr. A. L. Tatum.

toxicity In order for the clinician to use a drug intelligently he must know the manner in which its effects are brought about The plan of procedure and the details of the tests to be employed should be formulated in accordance with the type of agent to be investigated, e g single chemical entity, complex extract, hormone, serum or vaccine The conditions in which the drug is thought to be useful and the observations made in the preliminary testing will also modify the plan of investigation and the details of the test procedures Nevertheless we feel that the following general types of study should prove to be applicable to most new drugs keeping in mind that these are suggestive and not necessarily exhaustive

(A) *Biochemistry*—General properties of drug, including solubility, stability, studies of absorption, reabsorption, fate, distribution and excretion of the drug, quantitative data on these points where possible, mode of detoxification (excreted unchanged, oxidized, reduced, acetylated?), effect on enzymes, blood and tissues, chemistry of body fluids and tissues, production of toxic products during course of metabolism

(B) *Pharmacodynamics*—Local Tests of irritation on skin, eye, alimentary canal, intradermal irritation, sensitivity or anesthesia, tests of protoplasmic depression or toxicity, and reversibility of effects on cilia, nerve trunks, mucosa, hemolysis, anthelmolysis and blood pigment changes

Systemic Action on blood pressure, respiration, muscles, nervous system, cardiac functions, secretions, temperature, voluntary activity, organ perfusion, isolated tissues, effects of vasomotor agents, proteins, fats, metals, solvents and other agents on the actions of the drug, cumulative effects, development of tachyphylaxis, quantitative and qualitative differences in action in different species of animals

(C) *Experimental Functional Pathology*—Effects in experimentally induced pathologic states, e g smooth muscle spasm, hypodynamic hearts, fibrillations and arrhythmias, hypertension, respiratory depression, edema, shock, burns, anemias

(D) *Chemotherapeutic*—Effects in preventing specific experimental infections, effects in combating experimental infections or actions of toxins, antagonists of chemotherapeutic agents, e g pus, serum, tissue products, distribution in inflammatory states, e g meningitis, dermatitis, minimal effective dosage (ED50)

The data obtained from these studies will serve as a guide in the clinical application of the product and doubtless will also show evidence of undesirable or potentially harmful effects If such effects are not observed, a careful search must be made for them This involves the very important study of the toxicology of the preparation Woodard and Calvery,² Calvery⁴ and Draize, Woodard and Calvery⁵ have set forth in considerable detail the approach to the study of the acute and chronic toxicity of drugs and other chemical agents Certain of the principles which they have formulated bear repetition here, and the original publications can be consulted for more detailed discussions

Depending on the conditions for which the product may be used, on its biochemical and pharmacodynamic actions and on the methods of its use, adequate studies of its toxicity must be made The following outline sets forth in general terms the scope that these studies should embrace

(A) *Acute Toxicity*—Dosage response curves in three or more species, objective symptoms, statistical calculations for comparative studies, simultaneous comparative determinations of other substances, variations in toxicity with method of administration

(B) *Subacute Toxicity*—Large daily doses to one or more species for six to twelve weeks, microscopic pathology

(C) *Chronic Toxicity*—Three or more species, at least one species for the life of the animal, several dosage levels graduated to produce from no effect up to pronounced lesions, and possibly shortening life span, microscopic pathology, effects on voluntary activity, e g running or other performance as evidence of more subtle functional changes

(D) *Local Effects*—Sensitization, skin irritation, mucous membrane irritation, photosensitization

(E) *Special Studies*—Reproduction, distribution and storage, effect of diet, effect of environment, kidney and liver function tests

In selecting animals for investigation of new drugs it is important to use several distinct species, since it is well known that qualitative as well as quantitative differences exist between animal species in their reactions to drugs Some species are wholly unsuited for demonstration of certain effects, e g methemoglobin is not readily produced in rodents and if the drug is suspected of causing this reaction rats, rabbits and guinea pigs are not suitable test animals Rabbits are not usually satisfactory animals for blood pressure studies and often react atypically, e g histamine produces a rise of pressure instead of a fall Emetics cannot be tested in rodents, since vomiting does not occur in these species Many other examples could be cited, but these suffice to demonstrate the need for careful selection of suitable test animals

Each investigator, including those concerned with clinical as well as laboratory investigations, should realize from the beginning where each specialty fits in the over-all plan of study, e g chemistry, pharmacology, physiology, pathology He should keep a careful record of all data and not be guided solely by impressions The records should include actions not seemingly connected with the immediate project and dramatic response, for example, micturition, defecation, vomiting, pulse, respiration

After completion of the experimental studies, a critical review of the accumulated data should be made The purpose in this review is to reach a decision as to whether clinical trial of the drug is justified It is difficult to set forth criteria on which this decision should be made, since the judgment of the investigators must always be an important factor However, without any claim for completeness, the following points should be considered

1 Has the drug definite and desirable pharmacodynamic or chemotherapeutic actions?

2 Are its actions constant and reproducible?

3 Are these actions observed in different species of animals?

4 Is the mechanism by which its actions are produced a desirable one, or are the actions the result of an ultimately undesirable reaction of the animal?

5 Are the effects obtained in animals in which experimentally produced pathologic or functional changes comparable to human diseases have been made?

6 What is the therapeutic index of the compound (ratio of effective dose to toxic dose ED50/LD50)?

⁴ Calvery Herbert O. Safeguarding Foods and Drugs in Wartime, *Am Scientist* 32 103 119 1944

⁵ Draize John H., Woodard Geoffrey and Calvery Herbert O. Methods for the Study of Irritation and Toxicity of Substances Applied Topically to the Skin and Mucous Membranes to be published

7 Are the undesirable side actions of sufficient importance and severity to militate against its clinical use?

8 Is there an adequate margin of safety in its use?

CLINICAL OBSERVATIONS

When sufficient information regarding the experimental actions of a new drug has been obtained to permit a logical decision to be reached that clinical trial is indicated, such studies may be commenced cautiously. The primary objectives to be reached in clinical investigation are twofold (1) to determine the therapeutic efficacy and (2) to detect all signs of clinical intolerance or toxicity. The secondary, but nevertheless important, objectives are (1) to establish the effective dosage range for different age groups and conditions, (2) to determine the type and extent of collateral treatment necessary to obtain the maximum benefit from the drug, (3) to determine the best method of minimizing any undesirable side actions incident to the use of the drug and (4) to determine the contraindications and precautions to be observed in the use of the drug. Each clinical investigator should keep these objectives clearly in mind throughout his investigation in order that nothing may be overlooked.

Frequently the pharmaceutical manufacturer concerned with the development of a new product has neither the facilities nor the personnel to investigate the drug adequately. This is particularly true of clinical investigations. This work must be undertaken by others in cooperation with the manufacturer. The selection of the investigator is important and it is a waste of time and money and may even be dangerous to place the investigation of the safety and efficacy of a new drug in the hands of incompetent or poorly trained individuals. Furthermore, it is important to select the investigator who has proper qualifications and training in the particular phase of the problem requiring study. A good pharmacologist is not necessarily a competent pathologist, a specialist in internal medicine may not be in a position to evaluate a product offered for nasal or sinus infections. Furthermore, not all specialists in clinical medicine are capable of conducting acceptable clinical investigations. The caliber and training of each investigator should be carefully considered before putting a problem in his hands. Clinical investigation of a new drug presents many very difficult problems. The heterogeneity of the persons under observation, the difficulty of securing adequate controls, the many extraneous and uncontrollable factors, the constant presence of subjective effects influenced by conscious or unconscious bias and many other unique conditions hamper the investigator in his efforts to secure the truth. Regardless of these, it is possible to suggest certain factors to be given consideration in conducting clinical investigations.

(a) *The Selection of Individuals to Be Observed*—Cooperation from subject, absence of complicating factors, age, sex, emotional and psychic factors.

(b) *Diagnosis*—Objective proof of diagnosis if possible, such as isolation and identification of infecting organism, x-ray evidence or other informative laboratory data, accurate description of lesion, differential diagnosis.

(c) *Control Observations*—Preliminary control observations on the individuals; concurrent observations of untreated controls, alternation of treatment, alternation of treated and control subjects, post-treatment control observations.

(d) *Observation During Treatment*—Repeated physical and laboratory examinations, hematology, urinalysis, blood chemistry, x-ray, functional tests, precise objective measurements of improvements alleged to be produced by drug, determination of concentration of drug in blood, urine and other body fluids and the correlation of levels so observed with the dosage and the effect.

(e) *Number of Subjects*—Sufficient number of treated individuals to minimize chance or other uncontrollable factors from influencing results, sufficient number of untreated control subjects. The results should be subjected to statistical analysis in order to determine their reliability.

(f) *Carefully Planned Administration of Drug*—Controlled variation in dosage, frequency, method and duration of administration; effect of other drugs, and so on.

(g) *Criteria of Benefit*—Establishment of criteria whereby the effects of the drug may be evaluated, objective tests, subjective observations, comparison with control treatments, comparison with natural course of disease.

(h) *Separation of Subjective and Objective Observations*—Use of "blind tests" (neither investigator nor subject knows which of several samples being administered is control or test product) or other methods to eliminate conscious or unconscious bias on part of observer and subject, careful separation of symptomatic reactions from objective findings, psychologic appraisal of subject.

(i) *Duration of Observation*—Treatment to continue until any intrinsically undesirable or harmful manifestations have had time to develop as well as until sufficient time has elapsed to demonstrate beneficial effects, comparison of rapidity of cure or improvement with that of other methods of treatment.

(j) *More Than One Clinical Investigation*—Several different investigators working independently, conclusions to be made independent of one another's results.

When the investigator is satisfied that he has a therapeutic agent which may be given satisfactorily by one route he should not by conjectural reasoning alone decide that it may be given safely and effectively by some other route. For example, if a product is safe and efficacious for oral use it may not be so when administered by rectum or by injection.

If it is decided to have several persons working on the clinical aspects of the problem, each one should provide a complete picture of the phase under investigation and not just a piecemeal study. Above all, it should be realized that summaries of case histories unless accompanied by the full report from which the summaries were derived are of little significance. A multiplicity of fragmentary case reports provide less information than a few complete and detailed reports of cases carefully and critically studied.

On completion of the clinical investigations it should be possible to provide definite answers to the questions implied in the statement of the objectives which were set forth at the beginning of this section. If these answers are not forthcoming from the data, more investigation is necessary. However, with the fulfillment of the objectives it is now necessary to decide whether the new drug has sufficient merit to be used in the alleviation of human suffering and in the treatment, prevention or cure of disease. At the same time thought should be given to providing adequate warnings against use in certain pathologic conditions or against unsafe dosage or methods or duration of administration or application.

EVALUATION OF RESULTS

Two factors enter into the decision with regard to the merits of the drug 1 Is it efficacious? 2 Is it dangerous? Neither of these factors can be separated one from the other and considered alone This has been emphasized by Van Winkle⁶ in discussing the evaluation of new drug applications submitted under the new drug provisions of the Federal Food, Drug and Cosmetic Act It has been emphasized that there is no arbitrary standard of safety, it is a relative matter in which the toxicity of the drug must be weighed against the therapeutic benefits which its use will bring about Drugs with potentialities for harm and with only slight therapeutic effectiveness may be too dangerous for use, whereas another drug with the same potentialities for harm but with exceptional therapeutic usefulness may be relatively safe Therefore, in evaluating the results of the clinical and experimental studies of a new drug, the following factors should be considered

- 1 For what conditions is the drug to be offered?
- 2 How effective is it in these conditions?
- 3 Is it superior to other drugs and methods of treatment?
- 4 What is its inherent toxicity?
- 5 Does its toxicity outweigh the therapeutic advantages, keeping in mind the seriousness of the conditions for which it is being offered?
- 6 If there are other drugs equally or more effective in the same conditions, is the new drug less toxic or does it offer advantages in ease of administration, duration of action and so on?
- 7 How extensive will the use of the drug be, are its applications limited?

SUMMARY

A study of this outline for the therapeutic and toxicologic appraisal of new drugs may leave the impression that the task which has been set is far too complex and difficult, requires too much time and expenditure of energy and money and can be circumvented by briefer and less thorough investigations While this may be true in a few isolated instances, it is not true in the majority of cases of really new drugs Recent history contains too many instances of disastrous results that have followed incomplete or inadequate investigations on new drugs This outline is an objective toward which investigations of new agents should be directed It need not apply in full to all cases, but the reasons for omitting any part should be that the omitted parts of the program are not necessary and not merely that they are troublesome It should also be borne in mind that new methods and new criteria may be developed and these should, of course, be applied when indicated

Finally it is necessary to exercise sound judgment in deciding whether a product deserves recognition, and the only basis on which such a judgment can be made is by a careful appraisal of the data obtained through a systematic study Investigations of new therapeutic agents are perhaps the most exacting of all scientific investigations since human health, and even life, may depend on the thoroughness of these investigations Furthermore, failure to interpret correctly the results of the tests conducted and criteria for their evaluation may be disastrous

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies A copy of the rules on which the Council bases its action will be sent on application

AUSTIN SMITH, M.D., Secretary

HEXESTROL—Meso-3,4-di-parahydroxyphenyl-n-hexane, $C_{18}H_{26}O_2$ (M W 270.36) Hexestrol may be represented by the following structural formula

It may be prepared from anethole in ether solution by (a) treating with anhydrous hydrogen bromide to form anethole hydrobromide, (b) conversion of the anethole hydrobromide to 3,4-dianisylhexane by means of metallic magnesium aluminum, copper or zinc turnings and (c) hydrolysis of the 3,4-dianisylhexane to form hexestrol The product thus obtained may be purified by recrystallization from dilute alcohol

Actions and Uses—Hexestrol is used for the same conditions for which estrogenic substances are employed It is claimed to cause a lower incidence of toxic symptoms than those which follow diethylstilbestrol administration

Dosage—As is the case with all estrogenic substances, the dosage of hexestrol must be adjusted to the individual case As a guide the following dosages may be satisfactory For menopausal symptoms, 20 to 30 mg daily by mouth until symptoms are under control, and then 0.2 to 10 mg daily as a maintenance dose, or by injection, 10 mg in oil three times weekly with similar lowering for maintenance of control For gonorrheal vulvovaginitis the drug may be given orally in 30 mg doses three times daily for seven days, senile vaginitis and kraurosis vulvae, 2 to 3 mg daily by mouth, or 1 mg in oil three times weekly by injection suppression of lactation, 150 mg one to three times daily for two or more days, or 150 mg in oil daily for two or more days by injection

Tests and Standards—

Hexestrol occurs as an odorless white crystalline powder which melts at 183-188 C It is freely soluble in ether soluble in acetone ethanol and methanol slightly soluble in benzene and chloroform practically insoluble in water and in dilute mineral acids It may be dissolved in vegetable oils and in dilute solutions of sodium or potassium hydroxide When recrystallized from diluted alcohol hexestrol appears in the form of thin platelike crystals of irregular serrated outline

Dissolve about 10 mg of hexestrol in 10 cc of dilute alcohol and add three drops of 1 per cent ferric chloride solution a yellowish green color develops which changes to yellow Add a few drops of 50 per cent solution of antimony pentachloride in dry alcohol free chloroform to a very dilute solution of hexestrol in the same solvent a red colored solution is produced Dissolve 10 mg of hexestrol in 5 cc of concentrated sulfuric acid no color is produced (distinction from diethylstilbestrol which yields an orange color)

The hexestrol diacetate obtained in the assay given below melts at 137-139 C

Dry an accurately weighed specimen of hexestrol to constant weight at 100 C the loss does not exceed 0.5 per cent Ignite an accurately weighed specimen of hexestrol after the addition of concentrated sulfuric acid the sulfated ash residue is not more than 0.05 per cent Dissolve 0.1 Gm of hexestrol in 10 cc of warm normal sodium hydroxide solution the solution is clear and colorless dilute to 20 cc with distilled water and add 5 drops of 10 per cent sodium sulfide solution the darkening produced does not exceed that of a control to which has been added 0.02 mg of lead

Transfer to a suitable flask about 0.5 Gm of dried hexestrol, accurately weighed and add 2 cc of acetic anhydride and 4 cc of dry pyridine Boil the mixture under a reflux condenser for fifteen minutes cool add 50-60 cc of distilled water and shake the flask and contents thoroughly Stopper the flask and place it in the cold for one to one and one-half hours Collect the precipitate on a suitable filter and wash it with four 20 cc portions of distilled water Dry the precipitate at 75-80 C overnight cool and weigh the weight of the dry hexestrol diacetate obtained when multiplied by 0.7628 corresponds to a hexestrol content of not less than 98.5 per cent and not more than 100.5 per cent

SATURDAY, DECEMBER 9 1944

RESEARCH ON BRUCELLOSIS IN LATIN AMERICA

Two monographs recently published indicate that attention is being paid to brucellosis by Latin American workers. One, issued in 1942, is by Dr M Ruiz Castañeda,¹ the Mexican author better known for his studies on typhus fever, the authors of the other are Drs Purriel, Rizzo and Espasandín from Montevideo, Uruguay.²

One may wonder whether after such recent and comprehensive monographs on the same subject as those by Huddleson (1940) and Harris (1941) from this country such publications were really necessary. The answer is emphatically in the affirmative. The natural tendency of the authors to emphasize the contributions of their fellow countrymen and to describe more in detail what they have themselves observed makes of their writings precious documents for the knowledge of the history and geographic distribution of a particular disease. Thus one learns from the book by Purriel and his collaborators that in Uruguay, as in England and Denmark, the melitensis variety of Brucellosis is absent whereas the abortus variety is quite prevalent, a fact explainable on account of the great prevalence of bovine over caprine herds. Morbidity for the population at large is rather low while mortality is nil. The disease in nearly all cases is of a professional type, the incidence varying in direct relation to the association of men with cattle slaughtered in the several slaughtering houses or packing houses in the republic. The infection among cattle is high, the incidence being in a direct ratio with the degree of domesticity of the animals. Milk-producing cows show 50 per cent of infection. Keeping in mind that abortion occurs at least once during the lifetime of an infected cow, and the considerable subsequent diminution in milk secretion, one will realize the economic importance

of the disease in a country having a bovine population of from 7 to 8 million and where the milk of 50,000 cows is needed to supply the needs of its capital.

From Castañeda's monograph one learns that the state of affairs in Mexico is entirely different from that in Uruguay. In Mexico the vast majority of cases of human brucellosis are induced by the melitensis variety (95.2 per cent) whereas 3.5 and 1.3 per cent were induced by abortus and suis respectively. The infection in goats is suspected to be high although exact data are lacking, that of cattle varies from 25 to 50 per cent and that of swine is about 35 per cent. Human infection in Mexico is of a widespread and patchy type. Precise data are lacking but it may be assumed that at least 3 per cent of the population has been or is infected.

The increasing social importance of brucellosis is being now realized throughout the world, and Latin American republics are not found napping in this respect. Brucellosis in Mexico and Uruguay was first demonstrated only in 1920 and 1928 respectively. Despite that, a special commission appointed by the government has been functioning in Uruguay for several years, while three medical meetings devoted exclusively to brucellosis have been held in Mexico.

Besides supplying the information on which we have commented, the monographs are valuable in several other respects. The bacteriologic, immunologic and clinical angles of the disease are exhaustively covered, valuable data are given on the choice of the best laboratory methods and new personal technics are described.

A NEW VECTOR FOR ST LOUIS ENCEPHALITIS

The experimental transmission of the virus of St Louis encephalitis to chickens and pigeons by nine species of mosquitoes,¹ coupled with demonstration of the virus in local *Culex tarsalis* during epidemic periods,² suggested to earlier investigators that mosquitoes are the main if not the sole insect vectors of this disease. In a survey for the presence of type specific antibodies in the human and animal populations of the St Louis area, however, Smith³ and her associates of Washington University School of Medicine observed that few individuals who had come into St Louis County since 1937 showed specific antibodies while a large percentage of the local domestic fowls approximately 1 year of age were carriers of neutralizing antibody. This suggested that some blood sucking vector that does not bite man is mainly responsible for the spread of the virus among domestic fowls.

2 Purriel P Rizzo R and Espasandín J Brucellosis Estudio de esta enfermedad en el Uruguay Montevideo Editorial Independencia 1944

Blattner⁴ had previously shown that certain ticks (*Dermacentor variabilis*) are capable under experimental conditions of becoming infected with the virus of St Louis encephalitis and of transmitting it by bite to susceptible animals. Smith therefore turned her attention to the common chick mite *Dermanyssus gallinae*, a frequent parasite on fowls of the St Louis area. This mite belongs to the same order of Arachnida as the tick. Its life cycle is similar to that of the tick, since both require a blood meal before molting and before egg laying by the female. Mites were therefore collected from coops in which there were 2 or more chickens whose serums contained specific neutralizing antibodies. The mites were stored in test tubes for from seven to thirty days without feeding.

In one experiment at the end of seven days' storage, 60 mites were triturated in an agate mortar in tryptose broth, and 0.1 cc of the supernatant fluid was inoculated intraperitoneally into 11 to 19 day old Swiss mice. In a typical group 2 of the 6 inoculated mice showed signs of illness with slight twitchings or beginning convulsions on the eighth to the ninth day. These 2 mice were killed and their brains emulsified in 10 volumes of tryptose broth. After centrifugation 0.03 cc of the resulting supernatant fluid was inoculated intracerebrally into each of 8 mice. Three days later all 8 mice developed convulsions, from which 5 died before the close of the day. From the bacteriologically sterile brains of the 3 remaining mice (now moribund) the infection was passed by the same technique to a second group of 8 mice, all of which developed convulsions by the third day.

Egg membranes inoculated with brain supernate were bacteriologically sterile but appeared slightly thick and opaque by the third day. Mice inoculated intracerebrally with a Berkefeld filtrate from such membranes developed typical convulsions by the third day. Microscopic examinations of the brains of these mice show an encephalitic process indistinguishable from the pathologic picture of St Louis encephalitis in the mouse. Neutralization tests with specific antisera showed that the virus in the chick mite is qualitatively identical with the standard laboratory strain of the virus of St Louis encephalitis originally isolated from a human case.

Blattner⁴ found that ticks infected with encephalitis can transmit the virus to their offspring for innumerable generations. Assuming that a similar hereditary transmission of the virus takes place in infected mites, Smith concludes that infected mites may well account for the permanence of the viral infection in domestic fowls of the St Louis area. From these fowls sporadic human cases of mosquito borne encephalitis might readily occur. Recognition of the mite as an inter-fowl vector, therefore, may well lead to practical methods of reducing the number of sporadic human cases.

CONGENITAL MALFORMATIONS

The embryologic explanation of a common congenital malformation, even if known, is often not readily accessible to the pathologist or surgeon. Three recent important contributions to early human embryology have just been reported by Bremer of Harvard.

The first of the series,¹ on the embryology of congenital aneurysms of the cerebral arteries, was the outcome of interest inspired by the untimely death of Dr Soma Weiss. Two types of congenital aneurysms of the cerebral arteries are described by Bremer and their origin is traced. The first type he ascribes to the consequence of the rapid growth of the cerebral hemisphere during fetal life, which spreads the forks of the branches of the cerebral arteries which approach from the lesser curvature of the expanding hemisphere. If the forks of these branches of the cerebral arteries should lack media, the rapid spread may cause local aneurysms. The second cause Bremer found to be enlargement of the proximal portion of the plexuses formed from branches of the cerebral arteries which dip into the brain substance. If the enlargement persists while the distal communications degenerate, aneurysmal pouches from the main vessels may be formed.

The second paper,² on the diaphragm and diaphragmatic hernias, was the outcome of Dr Bremer's attendance at clinical pathologic conferences at the Children's Hospital, Boston. This important contribution to its embryology opens with a detailed consideration of the development of the diaphragm. "of which there is, to my mind, no adequate description."

The defects of the diaphragm are divided into several groups. The first is concerned with the last step in the development of the membranous portion: fusion of the two sets of diaphragmatic muscles (costal and lumbar) peeled off the body wall. Irregularities in the growth of pleuroperitoneal membrane produce a hernia recognized by its position lateral to the dorsal lobe of the liver, failure of the normal cutting off by the crural muscles of the infracardiac bursa may leave an open communication from the superior recess of the lesser peritoneal cavity into the right pulmonary ligament. These are true congenital hernias. Through additions to our knowledge of the development of the diaphragm, Bremer has completely classified the nature of its congenital defects and has provided an accurate nomenclature to replace the confusion so often characterizing discussions concerning hernias of the diaphragm.

The third paper,³ on anomalies of the intestinal tract, "duplication" or "reduplications," "enteric cysts" or "enterogenic cysts," "ileum duplex" and "giant diverticula," is also the result of investigations inspired by attendance at clinical pathologic conferences. Bremer divides these abnormalities of the intestinal tract into

2 Bremer J L. The Diaphragm and Diaphragmatic Hernia. *Arch Path* 36: 539 (Dec) 1943.

3 Bremer J L. Diverticula and Duplications of the Intestinal Tract. *Arch Path* 35: 132 (Sept) 1944.

4 Blattner R J and Heys Florence M. *J Exper Med* 79: 439 (April) 1944.

two groups on the basis of embryologic origin. Most of the spherical cysts are derived from true diverticula, which are found frequently on the antimesenteric surface of the intestine in embryos of eight to nine weeks. When normal absorption of these diverticula does not take place they may continue to grow and so bulge within the lumen, if restricted by muscle layers, or expand outside the bowel if the muscle wall is pierced. In the second group are a few spherical and most of the tubular "cysts," and these Bremer regards as true duplications. These originate by an abnormal persistence of the vacuoles among the massed cells or 'solid stage' of the intestine, a phenomenon found under normal conditions in the embryo of six to seven weeks. By confluence of a chain of vacuoles a new channel is formed parallel to the original lumen. The intestinal layers grow between the two. These duplications which contain all the layers of the normal intestine, lie usually between the leaves of the mesentery. They may be isolated and cystic or they may communicate with the parent lumen. A study of the structure and origin of these duplications makes clear why it is impossible in most instances to remove the duplication without resecting the adjacent bowel.

The direction of Bremer's research activities in the freedom following academic retirement has been influenced by his realization of the kinds of knowledge most in current demand by pathologists and clinicians. These important advances in embryology have immediate practical application.

Current Comment

CELLULAR TRANSFORMATION

Under the influence of carcinogenic agents normal cells may be changed into cancer cells with the power of autonomous growth. This change is permanent and inheritable. So far no way has been found to turn cancer cells back into normal cells, hence success in the treatment of cancer depends on the removal or destruction of the cancer. Are there examples in biology of more or less similar cellular transformations? The answer is yes. In his instructive review of the mechanisms of cell transformations Haddow¹ discusses irreversible and inheritable mutations studied recently by different investigators in plants, in *Paramecium aurelium*, in tumor producing viruses and in pneumococci. The interconversion of specific pneumococcus types was first described by Griffith.² Now Avery and his co-workers³ have found that the transforming agent is a thymonucleic acid—a discovery of far reaching implications in biology. "Once transformation has occurred," writes Haddow, "the newly acquired characteristics are thereafter transmitted without any further addition of

the transforming agent." In other words, a change has taken place in the pneumococcus cells much like that in normal cells when transformed into cancer cells. Haddow concludes by pointing out that relationships like those mentioned "seem more than mere analogies and strongly suggest an underlying unity of principle in the growth and differentiation of organisms of the most highly diverse kinds."

PROGRESS IN THE TREATMENT OF TYPHUS FEVER AND OF ROCKY MOUNTAIN SPOTTED FEVER

The conditions caused by specific rickettsias, such as typhus and Rocky Mountain spotted fever, present striking etiologic, pathologic and clinical similarities. The course and the symptoms result largely from the widespread localization of the rickettsial organisms in the vascular endothelium. In a detailed study of the circulation in severe epidemic typhus in French Morocco Woodward and Bland¹ obtained evidence that circulatory collapse in typhus is mainly peripheral in origin and not due to primary cardiac failure. They demonstrated reductions in the blood volume and in blood proteins, especially albumin, and other alterations, all of which are explainable as due to the vascular lesions of typhus and increased capillary permeability. Emphasis is placed on the importance of general supportive measures to restore the volume and the quality of the blood. Harrell and his co-workers² have pointed out that supportive measures are not used as much as they should be in the treatment of Rocky Mountain spotted fever. They too emphasize the loss of volume and of proteins by the blood on account of the vascular lesions which may lead to peripheral circulatory collapse if the proper treatment is not given. Yeomans and others³ have reported on the effect of para-aminobenzoic acid in epidemic typhus in Cairo, Egypt. Under well controlled conditions they compared the clinical course of 20 treated cases with that of 44 control cases. Beginning with 4 to 8 Gm of para-aminobenzoic acid by mouth, 2 Gm was given every two hours or enough to maintain the concentration of the acid in the blood between 10 and 20 mg per hundred cubic centimeters until the rectal temperature remained at 99.5 F or less for twenty-four hours. These amounts were taken with ease by the patients and without any serious untoward effects. In patients who received the acid in the first week of illness the course of the attack was much less severe and considerably shorter than in "untreated" patients. The fact that para-aminobenzoic acid may have curative effect in human as well as in mice typhus³ directs attention to many problems for investigation. What effect will para-aminobenzoic acid and related compounds have on Rocky Mountain spotted fever and other rickettsial diseases?

MEDICINE AND THE WAR

ARMY

QUARANTINE BRANCH ESTABLISHED IN PREVENTIVE MEDICINE SERVICE

A quarantine branch, under the direction of Lieut Col Phillip T Kmes and in cooperation with the U S Public Health Service and the Navy, has been established in the Preventive Medicine Service of the Surgeon General's Office, to afford all possible protection against diseases and harmful pests which might be brought from foreign countries by military traffic. The new Army quarantine policy takes advantage of the Army immunization program and of the constant medical supervision of the soldier. Modern methods of immunization, it was stressed by the Surgeon General, offer great advantages from the standpoint of preventing the introduction of diseases into this country as well as protecting the health of the soldier. Army personnel routinely receive immunizations for smallpox, typhoid and paratyphoid fever and tetanus. Special immunizations are given, in accordance with instructions from the Surgeon General, for typhus, yellow fever, cholera and plague. The Army program also includes measures to prevent the importation of dangerous insects from abroad. Extensive insect control programs have been carried out about military stations and airports abroad, using the highly effective techniques and agents which have been developed.

Future developments in the field of quarantine will include greatly improved methods for the international notification of disease, along with improved health certification of travelers so that officials at ports of entry will have the necessary medical data for accurate judgment with the least possible delay to travelers. The extensive military program now being developed is expected to go far in demonstrating the value of new methods growing out of wartime medical progress.

BRIGADIER GENERAL JAMES S SIMMONS AWARDED WALTER REED MEDAL

The Walter Reed Medal was recently presented to Brig Gen James S Simmons, chief of the Preventive Medicine Service in recognition of meritorious achievement in tropical medicine. The Walter Reed Medal was established by the American Society of Tropical Medicine in 1934 to be awarded periodically in recognition of meritorious achievement in tropical medicine by an individual or an institution. The first award was made at the thirty-second annual meeting of the society in 1935, at which time one medal was presented to the widow of Walter Reed and one was awarded to the Rockefeller Foundation for its study and control of yellow fever. In 1939 the award was made to Dr William B Castle of Harvard University in 1940 to Dr Herbert Clark of the Gorgas Memorial Laboratory in Panama and in 1942 to the United States of Brazil 'for outstanding work in the eradication of *Anopheles gambiae* in Brazil' and posthumously to Dr Carlos J Findlay of Havana, Cuba.

HONOR DEAD OF SECOND A E F DIVISION

Armistice day ceremonies, sponsored by the Second Division A E F Association were held at the Second Division monument (17th Street and Constitution Avenue), Washington, D C, to commemorate the attack launched on June 6 1918 by the Second A E F Division which saved Paris and paved the way for the march to the Rhine. The fourth brigade of the division made up of Marines, Navy physicians dentists, hospital corpsmen and chaplains spearheaded the attack against the Germans at Belleau Wood.

Veterans of the Second A E F Division, composed of Army, Navy and Marine Corps units, are now serving as officers of the fifth and sixth regiments which fought at Guadalcanal,

Tarawa, Saipan and elsewhere. The ninth and twenty-third regiments, Second Division, U S Army also officered by Second A E F Division men, fought in Normandy and are still in action in Europe.

Rear Admiral Alexander C Lyle (DC), USN winner of the Congressional Medal of Honor in the first world war while serving with the Fifth Marines, Second Division, A E F represented Vice Admiral Ross T McIntire Surgeon General of the Navy, at the Armistice day ceremonies. Major Gen Dewitt Peck, assistant commandant of the U S Marine Corps, spoke in behalf of the veterans of the three services who comprised the Second Division, the first combined unit under a single command in American military history.

GENERAL LULL ADDRESSES GRAY LADIES

Speaking recently before the first graduation class of the hospital course for Gray Ladies held at the station hospital at Fort Belvoir, Virginia, Major Gen George F Lull, Deputy Surgeon General, emphasized the important relationship between hospital personnel and the sick soldier, with special reference to the soldier returning from overseas. The Gray Ladies constitute a Red Cross volunteer organization that perform various services for hospitalized men in the armed forces.

ARMY AWARDS AND COMMENDATIONS

Major Lloyd W Taylor

Major Lloyd W Taylor, formerly of Washington D C, has been awarded the Legion of Merit by Major Gen James L Frink, commanding general of the U S Army Services of Supply in the Southwest Pacific. The honor was bestowed on Dr Taylor for his work in late 1942 and early 1943 as supply officer of a medical unit serving combat troops in New Guinea. Suffering from illness and fatigue, Dr Taylor obtained badly needed medical supplies for American and Australian hospitals other than his own, in addition to doing his regular work caring for wounded men. He is now assigned to the Office of Chief Surgeon of the Southwest Pacific area, helping in the evacuation of patients from battle zones to Australia and the United States. Dr Taylor graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1941 and entered the service June 1, 1942.

Lieutenant Colonel Willis B Johnson

Lieut Col Willis B Johnson, formerly of Everett, Wash was recently presented the Bronze Star Medal. The citation accompanying the award read "From July 30 to Aug 28, 1943 at New Georgia, British Solomon Islands, he was in command of a medical battalion which moved from Guadalcanal into close support positions on New Georgia under enemy air and ground attacks. The effective evacuation and field treatment of casualties under the most trying conditions of terrain and weather during this operation were largely due to his high professional and military knowledge as well as his determination." Dr Johnson graduated from the College of Medical Evangelists, Loma Linda-Los Angeles in 1937 and entered the service Sept 16, 1940.

Captain Mark W Dick

The Bronze Star Medal was recently awarded to Capt Mark W Dick, formerly of Grand Rapids, Mich. His citation read "On March 12, 1944, at Bougainville, Solomon Islands, while enemy mortar shells exploded around him, he ran 40 yards and crawled under a barbed wire entanglement."

to reach a seriously wounded soldier. Finding that the nature of the man's wounds made it impossible to move him to the protection of a pillbox, he unhesitatingly exposed himself and stood in an upright position to administer medical treatment during the intense mortar barrage.' Dr Dick graduated from the University of Michigan Medical School, Ann Arbor in 1932 and entered the service May 6 1942.

Captain Richard D Roys

Capt Richard D Roys formerly of Seattle and now a company commander of a medical unit on an island north of New Guinea has been decorated with the Bronze Star for bravery in caring for the wounded under fire. Dr Roys already held the Silver Star awarded for bravery in action in New Guinea last year. He graduated from the University of Oklahoma School of Medicine, Oklahoma City in 1939 and entered the service Nov 14 1940.

Colonel Benjamin M Baker

Col Benjamin M Baker, formerly of Baltimore, has recently been awarded the Legion of Merit by General Douglas B MacArthur for 'exceptionally meritorious conduct in the performance of outstanding services in the South Pacific Area from April 20 1942 to June 13 1944.' Dr Baker graduated from Johns Hopkins University School of Medicine, Baltimore, in 1927 and entered the service in 1940.

Captain Salvatore L Pernice

The Bronze Star Medal for meritorious service in the Solomon Islands was awarded recently to Capt Salvatore L Pernice, formerly of Brooklyn. Dr Pernice was cited for his work in accompanying tanks into combat in order to study problems concerned with the evacuation of casualties from tanks. Dr Pernice graduated from Long Island College of Medicine, Brooklyn in 1928 and entered the service June 18 1942.

Lieutenant Colonel Byron B Cochrane

The following citation was recently conferred on Lieut Col Byron B Cochrane formerly of St Paul, previous to his promotion to that rank. For meritorious service in connection with military operations against the enemy from Jan 30 to Feb 8 1944. During the training stages for the Kwajalein operation Major Cochrane devised new and ingenious methods for the treatment and evacuation of casualties. His untiring

effort and devotion to duty resulted in a superior organization prepared to handle all casualties in the most efficient manner. During constantly changing situations and numerous attacks he displayed great zeal and initiative, which inspired his officers and men to greater effort in the treatment of the wounded. In order that he might properly supervise and carry out his duties, Major Cochrane made numerous trips to the front lines with complete disregard for his own safety. His resourcefulness made possible the immediate treatment and evacuation of the wounded thus saving the lives of many who would otherwise have died.' Dr Cochrane graduated from the University of Minnesota Medical School, Minneapolis, in 1938 and entered the service in February 1942.

Captain Willard E Goodwin

The Soldier's Medal was recently awarded to Capt Willard E Goodwin, formerly of Baltimore. The citation read 'He rescued an army nurse from a rough sea after she had been swept into a gorge on Feb 27, 1944 at New Zealand. He went to the aid of the helpless nurse who was being dragged against the rocks and had suffered painful injuries. Succeeding in swimming to her he assisted her out of the gorge to a sandy beach some 400 yards away. His prompt action was responsible for saving her life.' Dr Goodwin graduated from Tufts College Medical School, Boston, in 1941 and entered the service after completing his internship in 1942.

Captain Jarvis M Hyatt

Capt Jarvis M Hyatt, formerly of Dearborn Mich, has been awarded the Bronze Star Medal for meritorious service and disregard for his own personal safety in France on Aug 18 and 19 1944 in connection with military operations against an enemy of the United States. Dr Hyatt graduated from Wayne University College of Medicine, Detroit, in 1936 and entered the service Aug 13, 1942.

Captain Weldon T Ross

Capt Weldon T Ross, formerly of McMinnville, Ore has been awarded the Legion of Merit in the European theater of operations for 'exceptionally meritorious conduct in the performance of outstanding services from Sept 10 to Oct 20 1943.' Dr Ross graduated from Duke University School of Medicine, Durham, in 1938 and entered the service in 1941.

NAVY

GORGAS MEDAL AWARDED TO COMMANDER JAMES J SAPERO

The Gorgas Medal established in memory of Surgeon General William Crawford Gorgas in 1942 and sponsored by Wyeth, Incorporated Philadelphia was awarded this year to Comdr James J Saperio for distinguished service as an officer of the Medical Corps, United States Navy. The presentation was made by Frank F Law, vice president of Wyeth Incorporated at the annual dinner of the Association of Military Surgeons, held at the Hotel Pennsylvania, New York, November 3. Rear Admiral Harold V Smith, chief of the Research Division Bureau of Medicine and Surgery, U S Navy, acted as proxy for Commander Saperio.

The Gorgas Medal in 1942 in a threefold award went to Rear Admiral Edward R Stitt of the Navy Medical Corps and Brig Gen Frederick F Russell of Boston and Jefferson R Keen, former army surgeons. In 1943 the medal was awarded to Dr Hugh Smith Cumming, surgeon general United States Public Health Service retired.

NAVY NURSE RECEIVES MEDAL

Lieut Comdr Mary Martha Heck, Nurse Corps U S N who recently completed a tour of duty as officer in charge of the contingent of Navy Nurses in England was awarded the Bronze Star Medal for 'meritorious service' and untiring effort. The presentation was made by Admiral Harold R Stark, commander Naval Forces in Europe.

FIRST WHOLE BLOOD BANK ABOARD SHIP

In the past the distances that lay between advanced bases and new combat areas had eliminated the transportation of whole blood by sea. With this knowledge Capt John T Bennett, United States Navy Medical Corps Hattiesburg, Miss made a decision that was to save many lives. That decision created the first known blood bank to be water borne to the fighting front aboard a hospital ship. Success of this experiment depended on the ability of living blood to survive disturbances created by vibrating ship's engines and the rolling and pitching of the ship. It was known that ashore, under proper conditions whole blood could be kept as long as ten days. With the decision made, the commanding officer of shore garrisoned Marines at an advanced base in the Marshall Islands where the ship lay at anchor, was consulted. The medical officer asked for 100 volunteers. Over 300 men from the small marine garrison responded. One hundred were selected, came aboard gave their blood and assured a rich, floating blood bank. The following morning the ship was under way with her precious cargo and anxious hopes for the success of the experiment. The success of their efforts can now be seen. American fighting men who came aboard seriously wounded took the road to recovery. At Guam there was ample whole blood for required transfusions. No wounded fighting man went without whole blood if it was required.

NAVY AWARDS AND COMMENDATIONS

Captain Harry L Goff

An award of the Bronze Star Medal was recently conferred on Capt Harry L Goff, formerly of Pembroke, Ga, "for meritorious performance of outstanding services as medical officer on the staff of the commander of an amphibious force in both the preparation and the execution of the amphibious assault on the coast of France, June 6, 1944. Captain Goff was charged with the organization and training of medical staffs and the evacuation and care of both Army and Navy casualties during the assault. The high level of efficiency maintained in this service was due to Captain Goff's able planning and resourcefulness and contributed in a substantial manner to the success of the operation. The sound judgment, initiative and devotion to duty displayed by Captain Goff on this occasion reflect great credit on the United States Naval Service." Dr Goff graduated from Jefferson Medical College of Philadelphia in 1925 and entered the service June 8, 1925.

Lieutenant Joseph John Connor

The Bronze Star Medal was recently awarded to Lieut Joseph J Connor, formerly of Denver for service as set forth in the following citation: For meritorious service as medical officer attached to Boat Pool Eleven operating in the Solomon Islands Area on Nov 29 1943. Assigned the hazardous mission of accompanying a boat pool during the evacuation of a Marine battalion from a position several miles behind Japanese lines, Lieutenant Connor worked tirelessly in caring for the injured despite a constant barrage of enemy machine gun mortar and artillery fire. Although forced to work in complete darkness he carried out his task so skilfully and with such exceptional efficiency that no lives were lost. Lieutenant Connor's cool courage under fire and his heroic devotion to duty in the face of grave peril contributed to the saving of many lives, and his gallant conduct throughout the operation was in keeping with the highest traditions of the United States Naval Service. Dr Connor graduated from the University of Colorado School of Medicine Denver, in 1941 and entered the service in July 1942.

MISCELLANEOUS

BRITISH WOMAN ARMY DOCTOR
HONORED

Lieut Col Albertine Winner, R A M C, director of the Woman's Medical Services of the British army, was guest of honor at a dinner given recently by Major Gen Norman T Kirk, Surgeon General of the Army. Major Gen George F Lull, Deputy Surgeon General, acted as toastmaster. Colonel Winner spoke on the work of the British women in the British army, and Major Margaret Janeway, Office of the Surgeon General, talked on the activities of women in the Medical Department of the Army of the United States.

Colonel Winner's visit to this country included the annual meeting of the Association of Military Surgeons and an inspection tour of various WAC installations.

GERMANS TOLD TO EXPECT FURTHER
FOOD RESTRICTIONS

According to a dispatch in the *Stockholms Tidningen* reported recently by the Office of War Information, the German food ministry has stated that another reduction in bread, fat and sugar rations in Germany is imminent because the total supply had declined by one fifth since the loss of the eastern territories. It was also stated that livestock had already decreased to such an extent "that to increase meat rations as a substitute for reduced bread and fat rations was no longer feasible." One fourth of the entire German potato crop this year is needed for the manufacture of fuel, and 3,000,000 tons of sugar beets is necessary for making industrial alcohol, the dispatch also reported.

German weekly bread rations, already low, were scheduled to be cut by 7 ounces per person because of 'decreased imports' and a poor grain harvest, according to a recent Nazi DNB agency dispatch to the German press. Normal consumers were to get 78 ounces a week, or less than three quarters of a pound per day of the basic food staple.

NEW HOSPITAL CAR FOR USE IN
THE UNITED STATES

The first of a new type hospital car for use in the United States was opened for inspection in Washington, D C, recently. These new unit type cars are not converted pullmans but are designed and built as hospital cars. They are 10 feet longer, are air conditioned and accommodate 38 patients and attendant personnel. Each includes two rows of triple tiered beds, two compartments with 3 beds each, a stainless steel kitchen equipped with refrigeration, ice cream cabinet and coal range, a receiving room with 4 foot side doors for loading and unloading litter patients, two roomettes each with toilet and shower for the medical staff or seriously ill patients and a baggage compartment. The car also carries a modern pharmacy unit and sterilizing equipment, and in case of emergency either the receiving

room or one of the roomettes can be converted quickly into an operating room. The Glennon type, steel frame beds are adjustable and unoccupied center bunks can be dropped to provide seating accommodations for ambulatory patients.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Mayo General Hospital, Galesburg, Ill. Diseases of the Intestinal Tract—Medical and Surgical Diagnosis and Care. Drs Warren H Cole and Michael H Streicher. December 13.

Camp Ellis, Illinois. Malignancies in the Army Age Group—Medical X-Ray and Surgical Diagnosis and Treatment. Drs George J Rukstien and Alexander Brunschwig. December 13.

Chanute Field, Rantoul, Ill. Bone and Joint Infections. Dr Cly Howard Hatcher and Lieut Col Ralph Soto Hall. December 13.

Vaughan General Hospital, Maywood, Ill. Dermatologic Diseases. Drs Francis E Senear and James H Mitchell. December 13.

Fort Sheridan, Illinois. Conditions Affecting Glucose Metabolism. Dr Arthur R Colwell. December 13.

Percy Jones General and Convalescent Hospital, Battle Creek, Mich. Symposium on Convulsive Disorders. Psychiatric Approach, Major I L Turow. Neurosurgical Approach, Major Frank H Mayfield. Neurologic Approach, Lieut D B Foster. December 18.

U S Naval Hospital, Philadelphia. The Epileptic Personality. Dr Harold Palmer. December 29.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL December 2 page 903)

CALIFORNIA

Permanente Foundation Hospital, Oakland. Capacity 134 admissions. 3,693. Sidney R Garfield. Medical Superintendent (interns July 1945).

KANSAS

St Francis Hospital, Wichita. Capacity 450 admissions. 13,721. Sister M Oswaldine RN. Superintendent (2 interns 1 now 1 Jan 15 1945).

NEW YORK

Our Lady of Victory Hospital, Lackawanna. Capacity 185 admissions. 4,143. Sister M Bathilde. Superintendent (interns).
Crouse Irving Hospital, Syracuse. Capacity 245 admissions. 7,035. Miss Dorothy Pellenz. Assistant Superintendent (3 interns).

VIRGINIA

River Side Hospital, Newport News. Capacity 233 admissions. 5,578. Arthur H Perkins. Medical Superintendent (1 resident—mixed).

ORGANIZATION SECTION

Council on Medical Service and Public Relations

Meeting Held in Cincinnati

Representatives of the Medical Societies of Ohio, Kentucky, Indiana and West Virginia met in Cincinnati October 29 in response to an invitation from Dr. E. J. McCormick, a member of the Council on Medical Service and Public Relations.

Mr. J. W. Holloway, Acting Secretary of the Council, stated the program and activities of the Council, as encompassed in the six directives from the House of Delegates. Namely:

- 1 To make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people.

- 2 To inform constituent associations and component societies of proposed changes affecting medical care in the nation.

- 3 To inform constituent associations and component societies regarding the activities of the Council.

- 4 To investigate matters pertaining to the economic, social and similar aspects of medical care for all the people.

- 5 To study and suggest means for the distribution of medical service to the public consistent with the principles adopted by the House of Delegates.

- 6 To develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association.

Dr. Joseph S. Lawrence, director of the Washington office, was asked to outline the program of the Washington bureau which the Council is sponsoring. He said that the objective of the Washington bureau was not to be a lobby or to conduct a lobby but rather to be a center of information through which the states might receive information concerning actions of Congress and of government bureaus. He hopes that the relationship can be so streamlined that each state will through its appointed representatives, at all times be thoroughly informed with what is transpiring in Washington. He called attention to a series of hearings that Senator Pepper, chairman of the Senate Subcommittee on the Nation's Wartime Health Program, is holding. Printed copies of the proceedings of two (parts 2 and 5) of these hearings are available and contain exceedingly valuable information. It was recommended that each physician write to his Congressman requesting a copy of each. The Washington office will expect each of the state societies to discuss matters that are reported from Washington with its Congressmen.

Dr. Lawrence urged physicians to give careful thought to legislation in order that there may be unanimity of opinion in the Association. Physicians have the reputation of not being able to agree and Congressmen are inclined to take advantage of this divergence of opinion when it is to their interests. If we as an association are united in opinion we shall be able to effect an influence which cannot be ignored.

The question arose as to how the Council should determine what instructions to give the Washington office on pending legislation and whether the opinion should arise with the states or with the Council. A vote was taken which indicated that it was the sense of those present that the Council should decide whether or not legislation is inimical and that information should be passed on to the states which would then support such action as the Council outlined.

Dr. James R. Bloss of the Board of Trustees urged the members to pay more attention to the reports in *THE JOURNAL* of the Association's various activities. He stated that the Board of Trustees is heartily supporting the Council. Inquiry of the physicians in service, he reported showed conclusively that they will seek postgraduate opportunities when they are out of the service.

Dr. L. Howard Schriver, president of the Ohio society, confessed that the conference put him in an optimistic frame of

mind. He thought it an especially good sign that the American Medical Association had taken this advanced step of learning more intimately the feelings and opinions of its members. In his opinion the profession has been too passive, too academic. We should take a more active interest in social politics and teach our students to do so.

Dr. Elmer L. Henderson, a Trustee, replied to a complaint made by one of the physicians that communications directed to the Board of Trustees were not answered promptly and explained that the Trustees are not in continuous meeting and so delays should not be interpreted as showing a lack of interest. The board is a hard working body and gives consideration to every suggestion that is submitted.

Dr. Jonathan Forman of Ohio urged that special effort be taken to educate the public in health matters. The people want to be informed on the health conditions of their communities. More knowledge would obviate much muddled thinking and increase a desire for good health.

Dr. A. A. Brindley reported that a prepayment plan of insurance began functioning in Toledo on July 1, 1944 and in the first four months over 6100 contracts were written. 38 per cent on an employee only basis, 19 per cent on the employee and one dependent basis and 43 per cent on the family basis. The total number of people covered is 15,347. Thus far 473 claims have been paid. Maternal care is not included in the plan.

Dr. R. L. Sensenich, a Trustee, called attention to the pamphlet on medical service prepared by the Bureau of Medical Economics describing many sickness insurance plans now operating. Obviously no one person is wise enough to draft a plan for the whole United States that would be just the plan to fit any particular county or community. Large insurance companies are still experimenting with their problems. The states which have tried to establish insurance plans have met with varying degrees of success and failure. Before a plan can succeed there must be unanimity of opinion as to the type of plan wanted.

Dr. Barney J. Ham made a strong appeal for unanimity and then for leadership.

Dr. Robert E. S. Young of Columbus reported briefly on studies he has made of sickness insurance plans and of the philosophy back of them. He pointed out that government plans have a great political value, even industry finds other use for the power it gets in controlling its private plan than that of providing medical care. This control can be modified by the physicians if they unite to preserve their rights and study sympathetically the problems involved in developing a plan.

Dr. W. H. Howard reported on the plan Indiana is studying. Two sets of conditions present themselves. Should the plan be administered by the physicians or by an insurance company? Should it be on a service or on an indemnity basis?

At the close of the conference, late in the afternoon, many expressed themselves as feeling that the success of this conference justified the Council's efforts and as hoping that there will be other conferences in the future.

Society Proceedings

COMING MEETINGS

American Academy of Orthopaedic Surgeons, Chicago, January 21-24. Dr. Myron O. Henry, 825 Nicollet Ave., Minneapolis, Secretary.

American Society of Anesthetists, New York, Dec. 14. Dr. McKinnie L. Phelps, 745 Fifth Ave., New York 22, Secretary.

Annual Forum on Allergy, Pittsburgh, January 20-21. Dr. Jonathan Forman, 926 Bryden Road, Columbus, Ohio, Director.

Association for Research in Nervous and Mental Diseases, New York, Dec. 15-16. Dr. Thomas E. Bamford Jr., 115 F. 82d St., New York 28, Secretary.

Puerto Rico Medical Association of Santurce, Dec. 15-17. Dr. E. Martinez Rivera, P. O. Box 3866, Santurce, Secretary.

Society of Surgeons of New Jersey, Jersey City, January 31. Dr. Walter B. Mount, 21 Plymouth St., Montclair, N. J., Secretary.

Washington Letter

(From a Special Correspondent)

Dec 4, 1944

Labor Plans Social Security Legislation

Plans of the two major labor unions with regard to the Wagner-Murray-Dingell bills now pending in Congress, which provide "everything in social security, including the kitchen sink," are to split the bills into four or five separate proposals, to replace the omnibus measure, according to union spokesmen. These plans, of course, have yet to be cleared with Congressmen who have the say in the matter.

The extension of old age and survivors' insurance to the "missing 20 million" not now covered by social security would be put up to Congress in a separate bill from others dealing with such controversial questions as "socialized medicine" and federalization of state unemployment insurance systems. The Wagner-Murray-Dingell bills have been in Congressional committees for a year and a half without hearings. It is believed that favorable action can be obtained on parts of the bills by divorcing them from the proposals which aroused strong group opposition.

Civil Services Hire Disabled Vets Quickly

Dr. Verne K. Harvey, medical director of the Civil Service Commission, revealed to the House Committee to Investigate Aid to the Physically Handicapped that Civil Service is now prepared to place disabled veterans in government jobs quickly and effectively. This was accomplished through analyses of 41,823 handicapped persons placed in government jobs since Oct. 1, 1942 and study of thousands of jobs. Duties are classified to the point where it has been determined how many fingers will be required for specific jobs. Positions have been listed which can use persons who have disabilities in arms, legs, vision and hearing. Dr. Harvey said that much had been done through the Coordinating Committee for the Placement of the Physically Handicapped, a joint committee representing the Civil Service Commission, Federal Security Agency, Council of Personnel Administration, Veterans Administration and the Veterans Employment Service.

Maryland and District in Licensing Squabble

Action of the Maryland Board of Medical Examiners in refusing to grant a Washington doctor a \$1 "borderline" certificate entitling District of Columbia physicians to practice in nearby Maryland has precipitated a controversy here. The District Commission of Licensures may retaliate December 11 by revoking \$1 "courtesy" certificates entitling Maryland doctors to practice in the Capital. Dr. George C. Ruhland of the District health office and the executive board of the District Medical Society have criticized the action of the Maryland board at a time when there is reported to be a grave shortage of licensed physicians in adjacent Prince Georges and Montgomery counties of Maryland.

Mrs. Roosevelt Praises Epidemic Control

The notable achievement of the American medical profession in keeping down epidemics during this war was mentioned by Mrs. Roosevelt in her address at Pan American Health Day ceremonies here December 2. "In this war," she said, "a remarkable thing has been achieved in keeping us from epidemics which might have taken a heavy toll. By comparison, she recalled the influenza epidemic of the last war, which cost many lives and slowed up the war effort not only in this country but also in others."

Dr. L. S. Rowe, director general of the Pan American Union, said that scientific estimates showed that further health protection throughout the Americas would increase production by more than 30 per cent. Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, said that a permanent international health organization after the war is essential.

Among its possible functions, he said, would be collection and interchange of epidemic intelligence, standardization of biologic products including international standards of food and drugs, international action to train public health personnel through establishment of international schools of hygiene, commissions of experts to promote control of major diseases, health education, and scientific guidance on nutritional policies.

Charles M. Hay, deputy chairman and executive director, War Manpower Commission, assured delegates from other nations that all facilities of the United States would be available to carry out an international health program. Among Latin American speakers were Julian R. Caceres, Honduras, and Ambassador Don Pedro Beltran, Peru.

1944 Version of Townsend Plan Considered

Near the stage where it will be debated in the House is the "1944 version of the Townsend old age pension plan," a bill sponsored by Representative Pat Cannon, Democrat, of Florida. It differs from the Townsend plan in that it would levy a 3 per cent tax on the gross income of every individual and business, with \$100 monthly exemption for personal incomes. Under the earlier plan a 2 per cent tax on every business transaction except payment of wages or salaries was to provide the money. Later a 2 per cent tax on wages, inheritances and gifts and a 10 per cent increase in income tax were added. The old Townsend plan set a maximum pension of \$200 a month, but the Cannon bill does not specify the amount. Eligible for pensions under the Cannon measure would be all over 60, disabled under 60 and mothers taking care of children under 18. Pensioners would not hold jobs and would have to spend every monthly check within thirty days. Economists pointed out that \$200 a month for around 12,000,000 pensioners would cost close to \$35,000,000,000 a year and that taxes would increase retail prices and the cost of living.

Army Prepares for Heavy Casualties

The Army is anticipating a steady increase in casualties from overseas and is trying to provide a maximum of bed space in its general hospitals, which are equipped for most advanced types of medical and surgical attention. From its general hospitals it has started to move men who can get around and who do not need constant medical and surgical attention. Still unanswered is the question of whether the Army and Navy will continue to operate all the hospitals built for the services when the war is over. Alternative would be to turn them over to the Veterans Administration. Also undetermined is which hospitals will be turned back to civilian uses and which will be kept by the government as the number of hospitalized men decreases. The Army is expected to reveal soon an extensive program of convalescent hospitals for wounded veterans. Its main purpose will be to provide accommodation for thousands of long time convalescents able to walk and exercise.

Venereal Disease Control Advocated

Favorable editorial reaction to the conference on venereal disease concluded recently in St. Louis was expressed in the press of the Capital, with the Washington Post making a specific proposal that "the problem of controlling the disease seems to lie in finding a way to control it among women." Admitting the difficulties involved, it adds "But since few of the women who are now spreading the infection are professional prostitutes, the thing is much easier proposed than accomplished."

U. S. Backs Liberian Health Plan

The United States Public Health Service announces that an all Negro United States mission, including physicians, engineers, entomologists and nurses, soon will launch a five year health and sanitation program in Liberia, West Africa. The mission was organized at President Roosevelt's direction on request of the Liberian government and will be headed by Dr. John Baldwin West, senior surgeon, U. S. P. H. S.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Two Deaths from Mussel Poisoning—The quarantine established May 1 of all mussels from the ocean shore of California including the Bay of San Francisco has been extended until further notice as the result of 9 cases of mussel poisoning with two deaths in San Mateo County.

University News—Francis J W Roughton Ph D fellow of Trinity College Cambridge, and fellow of the Royal Society of London who has been working in the United States on aero medical problems, recently delivered a lecture in Wheeler Hall University of California, Berkeley on 'Some Recent Work on Carbon Monoxide as a Poison and a Physiological Tool'.

School Health Educator Named—The state department of public health announced the appointment as school health educator of Miss Bernice Moss, recently lecturer in public health education in the University of California School of Public Health. The state department of education is cooperating with the state department of public health in promotion of the school health education program. Miss Moss, who has a master's degree in health education will be available for consultant service in the state public schools.

Personal—Stanley B Freeborn Ph D, United States Public Health Service who after Pearl Harbor organized and administered the program of the public health service for malaria control in war areas has returned to his position as professor of entomology and assistant dean of the University of California College of Agriculture Berkeley—Dr Eberle Kost Shelton Los Angeles was recently given the honorary degree of doctor of science by the University of Colorado School of Medicine Denver where he graduated in 1911.

COLORADO

Personal—Dr Alfred Lee Briskman, assistant medical director of the Union Printers Home and Tuberculosis Sanatorium Colorado Springs has been appointed medical director at the Jewish Consumptives Relief Society sanatorium in Denver. Dr James H Riffey will succeed Dr Briskman at the printers home—Dr William H Crisp Denver was recently presented with a watch by the *American Journal of Ophthalmology* in appreciation of his long service to the journal and for outstanding contributions to ophthalmology.

Division of Industrial Hygiene Revived—A T Rossano Jr MS has been lent by the U S Public Health Service to the Colorado State Board of Health to serve as director of and to reactivate the division of industrial hygiene. The division became inactive more than two years ago when the entire staff was called into the armed services. The staff of the division will consist of an industrial hygiene engineer an industrial hygiene chemist and the part time services of an industrial physician and an industrial nursing consultant. A completely equipped industrial hygiene laboratory will be maintained for precise analyses of atmospheric samples materials and biologic fluids. Special field instruments for the rapid evaluation of occupational hazards will be available.

FLORIDA

Physician Fined \$10,000 for Narcotic Violation—On November 7 the Tampa *Tribune* reported that Dr Benjamin L White, St Petersburg had the previous day been fined \$10,000 and given a suspended sentence of two years and a day in a federal penitentiary after pleading nolo contendere to 26 charges of illegally selling narcotics. In addition to the fine and suspended sentence the physician was placed on probation for five years three of them under the supervision of a federal probation officer. Specific provisions of the probation were that he pay the fine within thirty days surrender his narcotic license and all narcotics and refrain from prescribing or dispensing narcotics in any form during his five years probation. The *Tribune* reported that Dr White admitted his guilt to a similar indictment of 28 charges ten years ago in Orlando but owing to his past record was allowed

to make a compromise settlement with the government of \$1,500. The case was heard by District Judge William J Barker, Southern District of Florida and the \$10,000 fine was said to be the largest criminal fine ever made in that federal court.

GEORGIA

New Quarantine Hospital—October 19 was to be the opening date for the new \$40,000 quarantine hospital in Atlanta. The new unit is located in a remodeled building at the city prison farm and is under the supervision of the city department of health. Dr James F Hackney is the city health director.

Personal—David F Marsh, Ph D, assistant professor of pharmacology University of Georgia School of Medicine, Augusta, has been appointed associate professor of pharmacology and head of the department at the West Virginia University School of Medicine Morgantown, effective December 31. Raymond P Ahlquist, Ph D has been appointed assistant professor of pharmacology at Georgia to succeed Benedict E Abreu Ph D.

Dr Paullin Honored—On November 21 the Atlanta Chamber of Commerce awarded its annual Certificate of Distinguished Achievement to Dr James E Paullin, former President of the American Medical Association. More than 200 persons were present for the ceremony, which included a dinner in the Onsey Hotel. The citation accompanying the award read:

To James Edgar Paullin in recognition of service practical in nature to the welfare of the people of this state and nation. For more than thirty seven years Dr Paullin has worked faithfully to improve standards in hospitals in the practice of medicine and in medical education. Testimony to the effectiveness of his work and its value to the medical profession has already been given by the distinguished medical societies of the country. It is fitting that his friends and neighbors show by this certificate that they understand and appreciate the value of his services to his own community.

Expansive Postwar Hospital Program—On recommendation by its health panel, the state agricultural and industrial development board of Georgia approved, November 9, a large expansion of facilities for medical care and hospitalization in Georgia as a postwar project. According to the *New York Times* the program contemplates the expenditure of \$22,545,000 local funds and \$5,275,000 state funds for the purchase or construction of hospitals and the provision of \$3,535,000 local funds and \$7,925,000 state funds for their operation. It also proposes buying 5,660 general hospital beds in fifty-three counties. The panel reported that eighty-six counties had no general hospital beds and only six counties had more than five beds in 1,000 population. It added that two counties did not have a resident physician and seventy-six had only one physician each in 3,000 population. The agricultural and industrial development board was created recently by the general assembly to coordinate existing agencies. Seven panels constitute the board, covering agriculture, education, government, health industry, public works and trade commerce and business. Members of the health panel include Dr Thomas F Abercrombie Atlanta chairman and Dr Rufus F Payne, Atlanta director. Headquarters of the board are located on the campus of the University of Georgia Athens.

ILLINOIS

Ninety Years of Age—Dr James M Mitchell, Oblong, celebrated his ninetieth birthday October 19 as the guest of the Crawford County Medical Society. Dr Mitchell graduated at the Hospital College of Medicine Louisville Ky in 1901.

Citizens Vote to Establish Health Departments and Tuberculosis Control—New health departments will be created in Adams and Du Page counties through the vote of the people in the recent election. In Adams County the vote passed by a three to one majority and in Du Page County by a three to two majority. This is said to be the first time that people of any county in the state have by popular vote established a county health department and levied a tax to support it. These two counties were the first to submit the provision to a vote under the new law popularly known as the Searcy-Clabaugh law. In Clinton and Edwards counties citizens voted favorably for the first time for a tax levy to provide for the care and treatment of their tuberculous citizens as provided by the Glackin and Excess Tax laws. Tazewell County already operating under the provisions of the Glackin law voted favorably on the levy of a special tuberculosis tax in excess of the ordinary tax limits. Nine other counties also voted favorably on the proposition some to legalize and some to continue the excess

tax levy for the control of tuberculosis. These counties include Bureau, Champaign, Clay, Hardin, Jasper, McDonough, Rock Island, Sangamon and Shelby. Of the 102 counties in Illinois, 83 have now voted favorably on a tax levy for tuberculosis control. The 19 remaining counties that have not voted a tax, and very few of which have tuberculosis control programs of consequence, include Brown, Calhoun, Edgar, Hancock, Jersey, Jo Daviess, Johnson, Lawrence, Marshall, Massac, Monroe, Perry, Pope, Pulaski, Putnam, Union, Wabash, Warren and Williamson.

Chicago

The Fenger Lecture—Col Esmond R Long M C will deliver the ninth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society at the Palmer House, January 8. His Subject will be "Tuberculosis as a Military Problem."

Symposium on Obstetrics—The Chicago Medical Society will devote its December 13 meeting to a symposium on obstetrics. The following will participate:

- Dr Theodore J Morris Diagnosis and Treatment of Puerperal Infection
- Dr William J Dieckmann Early Signs and Treatment of Toxemia of Pregnancy
- Dr Janet E Towne Prolonged Labor
- Dr Frederick H Falls Proper Use of Cesarean Section

MASSACHUSETTS

District Meeting—The Suffolk District Medical Society was addressed in Boston, November 18, by Governor Leverett Saltonstall on "Medical Social Security" and Dr Roger I Lee Boston, President-Elect of the American Medical Association, "Health Insurance."

Seventy Five Years of Public Health—The Massachusetts Department of Public Health is this year completing seventy-five years of service. According to Dr Vlado A Getting Boston, state health commissioner, in the *Norfolk Medical News*, the Massachusetts board was the first in America.

Licenses Revoked—At a meeting of the state board of registration in medicine October 18, the license to practice medicine of Dr Robert E Conlin, Woburn, was revoked because of gross misconduct in the practice of his profession as shown by his conviction in court and treatment of a patient. The license to practice was also revoked of Dr Morris J Kupper, Roxbury, because of gross misconduct in the practice of his profession as shown by collusion.

Riggs Foundation Observes Anniversary—The Austen Riggs Foundation, Stockbridge, commemorated its twenty-fifth anniversary with a meeting at the New York Academy of Medicine, November 22. The foundation, directed by a board of trustees, a medical advisory board and the Austen Riggs Associates continues in the village of Stockbridge the medical practice of the late Dr Austen Fox Riggs which was restricted to the care and treatment of mild nervous or functional disorders. Among the speakers were Dr Lawrence S Kubie New York who discussed the problem of brief psychotherapy and the training of therapists, Brigadier John R Rees, British army, and Major General George B Chisholm, Canadian army.

NEW YORK

Graduate Lectures—Richard C Arnold Surgeon U S Public Health Service, gave a graduate lecture on "Penicillin Therapy" before the staff of Veterans Memorial Hospital Ellenville, December 5, and Dr Julian Rose, Brooklyn addressed the Saranac Lake Medical Society, December 6, on "Diseases of the Biliary Tract." Dr William F Lipp Buffalo, will address the Jefferson County Medical Society in Watertown, December 14, on "Treatment of Jaundice." These lectures are sponsored cooperatively by the state medical society and the state department of health.

Personal—Dr Gilbert Dalldorf, director of the Grasslands Hospital laboratory Valhalla has been appointed director of the new Westchester Health Laboratory which is to be set up at Grasslands.—Dr Eugene Kisch New York associate in orthopedic surgery, Hospital for Joint Diseases Far Rockaway, left for Brazil in October to lecture on bone and joint tuberculosis and to attend conferences in Rio de Janeiro São Paulo and Bello Horizonte as the guest of the Brazilian Society for Tuberculosis.—Dr Moses A Stivers Middletown, has been appointed to the recently created position of medical consultant to the department of public welfare it is reported.—Dr John S Ware has been appointed chairman of the health committee of the Staten Island Council of Social Agencies.

New York City

Harvey Lecture—Dr Jean R Oliver professor of pathology, Long Island College of Medicine Brooklyn, will deliver the third Harvey Society Lecture of the current series at the New York Academy of Medicine, December 21. His subject will be "New Directions in Renal Morphology A Method, Its Results and Its Future."

Lectures to the Public—On November 9 the New York Academy of Medicine opened its tenth series of lectures to the public with a talk by Dr Iago Galdston on "Psychiatry in the History of Medicine." The opening address was designated the Linsly R Williams Memorial Lecture. Other lectures in the series which this year has been devoted to "Psychiatry in Medicine," include:

- Dr James H Wall White Plains N Y Development of Modern Psychiatry November 20
- Dr G Canby Robinson Washington D C The Patient as a Person December 19
- Dr Franz G Alexander Chicago Recent Trends in Psychiatric Thought and Future Outlook December 28
- Col William C Menninger M C War and Psychiatry January 11
- Dr Edward Weiss Philadelphia Psychotherapy in Everyday Medicine (George R Siedenburg Memorial Lecture) January 25

Presentation of Nobel Awards—On December 10 six of eight winners of the 1943-1944 Nobel Prizes in science and literature will receive awards amounting to \$120,000 at a luncheon in the Waldorf-Astoria Hotel. The occasion which is being sponsored by the American-Scandinavian Foundation, 116 East 64th Street, will mark the first time that the Nobel Prizes ever have been presented in the United States. The presentations will be made on behalf of King Gustav V by Wollmar F Bostrom, minister from Sweden. Recipients of the awards will be, among others, Henrik Dam, Rochester, N Y, and Edward A Doisy, Ph D, St Louis, for their work on vitamin K, Drs Joseph Erlanger St Louis, and Herbert S Gasser, director of the Rockefeller Institute for Medical Research for their work on nerves, and Isidor I Rabi, Ph D, and Otto Stern Ph D, Pittsburgh, for the results of their study of the structure of the atom.

Medical Societies Coordinating Council Considers Reorganization—A plan has been presented to reorganize the coordinating council of the five county medical societies of greater New York in order that official representatives of each group may form an authoritative body to represent the organized medical profession in the city. According to the *Journal of the Medical Society of the County of New York*, each county medical society is now completely autonomous, speaking for the profession only within its own boundaries. It may or may not take into consideration the interests of the four other county medical societies in the city. In matters of identical interest each society may take a stand either in agreement or in conflict with the interests of the other county medical societies or the action taken by them. While the coordinating council of the five county medical societies has been of service during the ten years of its existence the council has, however, lacked the authority and power to do more than advise or suggest. Under the recommendation to reorganize the council, it is proposed that each county medical society retain its autonomy within the state society but that it alter or amend its constitution and by-laws to grant certain definite powers to the coordinating council of the five county medical societies, electing to it annually three representatives, which under the new setup would be enabled to speak with authority on matters involving all the county medical societies generally but excluding matters of purely intracounty interest or import. Each county medical society would retain all powers not granted to the coordinating council. The proposal carries certain stipulations as to the method of action by the council in the handling and commitment of its powers. The functions of the council would be supported by contributions from each of the five county societies on a per capita basis according to the membership of each society and would have a headquarters office with a director and other clerical help.

PENNSYLVANIA

Society News—Dr Louis H Clerf, Philadelphia, addressed the Reading Eye, Ear, Nose and Throat Society, November 15 on "Cough Considered from an Otolaryngologic Viewpoint."—The Pennsylvania State Association for Health Physical Education and Recreation held its annual conference at the Schenley Hotel Pittsburgh, December 8-9. The address of the association is 231 Administration Building Forbes Street at Bellefield Avenue Pittsburgh 13.

Howard Petry Appointed Director of Mental Health—Dr Howard K Petry, medical superintendent of the Harrisburg State Hospital has been appointed director of the bureau of mental health of the Pennsylvania Department of

Welfare He succeeds Dr William C Sandy who retired from the position July 1 (*THE JOURNAL* August 12, p 1050). Dr Petry, who has been chairman of the committee on mental hygiene of the Medical Society of the State of Pennsylvania for many years and who recently was appointed by the governor as chairman of a committee to make a survey of conditions in the state's mental hospitals will continue to serve as superintendent of the Harrisburg State Hospital.

Philadelphia

Personal—Dr Harvey Bartle has retired as medical director of the Pennsylvania Railroad after forty-one years of service. Dr John A White, medical examiner for the company in Washington, D C, for a number of years, has been named to succeed Dr Bartle as chief medical examiner.

Schireson's Trial Scheduled for January—Hearing on the injunction sought by Dr Henry Junius Schireson to prevent the state from revoking his medical license has been scheduled for the January term of the Dauphin County Court, Harrisburg. The *Philadelphia Record* reported November 22. It was stated that Schireson was ordered by the state board of medical education and licensure last June to appear on July 10 and show cause why his license should not be revoked on the ground that it was obtained through fraud (*THE JOURNAL* May 27, p 297). Subsequent investigation by the state licensing board with the assistance of the attorney general's office disclosed that when Schireson applied for his license to practice in Pennsylvania in 1910 he pretended to medical qualifications he did not have. Schireson obtained a temporary injunction restraining the state from holding a hearing on the show cause order (*THE JOURNAL* September 9 p 116), contending that the state had no authority to revoke a license for fraud, it was stated. This action was taken in July and since then time has been spent in an effort to find a time convenient for the court for the state and for Schireson when arguments could be heard on the issue of whether the injunction should be vacated or made permanent.

TEXAS

State University to Remain at Galveston—The board of regents of the University of Texas at its recent annual session voted six to one in repudiation of a recent recommendation that the medical school of the university be moved from Galveston to Austin. The board also accepted an offer of the Sealy and Smith Foundation, Galveston, to give \$2,000,000 for construction of a new general hospital to provide more clinical material for the medical school.

Science Meeting—The Texas Academy of Science met in Galveston November 9-11 under the auspices of the University of Texas Medical Branch. Features of the session included a symposium on age changes in various tissues, symposium on health conditions in the coastal area of Texas, a discussion on the establishment of a marine biologic laboratory, several sessions on the conservation of natural and human resources and a symposium on the biology of the cancer cell.

Plans Approved for New Medical Building at Baylor—At a meeting of the board of trustees of Baylor University November 13 tentative building plans were approved for a new college of medicine building to be erected on the 20 acre site in the medical center. The proposed four story building will cost \$1,000,000. It will include an auditorium in the center wing and will house all the preclinical and administrative departments as well as offices for the members of the clinical departments. The \$1,000,000 for the new building and the 20 acre site are gifts to the college by the M D Anderson Foundation which has also provided \$1,000,000 for research to be used in the next ten years. In addition the college of medicine received \$500,000 for the same ten year period as a gift from the citizens and business firms of the city of Houston.

Personal—Dr Benjamin F Hambleton, professor of physiology and pharmacology, Baylor University College of Medicine, Houston, was recently awarded the honorary doctor of science degree in recognition of his long service in medical education and research. Dr Hambleton has been with Baylor since 1920. Previously he was professor of physiology and pharmacology at Vanderbilt University School of Medicine, Nashville, Tenn, where he also served as acting dean and secretary of the medical school during World War I.—Dr William W Looney, for many years professor of anatomy, Baylor University College of Medicine, Houston and recently professor and chairman of the department of anatomy, Southwestern Medical College, Dallas has resigned to enter private practice in Greenville.—Dr Edward F Yeager, Mineral Wells, was recently appointed medical director of the Baker Hotel, a newly inaugurated service for guests who register to take the baths and water.

VERMONT

Personal—Dr James C O'Neil on July 15 resigned as medical superintendent and treasurer of the Vermont State Hospital for the Insane, Waterbury.

State Medical Election—Dr Leon E Sample, St Albans, was chosen president-elect of the Vermont State Medical Society in October and Dr Frank J Hurley, Bennington, was installed as president. Other officers include Drs Paul C T Bacon, Springfield, vice president, David Marvin, Essex Junction, treasurer and Benjamin F Cook, Rutland, secretary.

VIRGINIA

Vaughan Memorial Clinic—The Vaughan Memorial Clinic is now being developed in Richmond as a memorial to the late Dr Warren Taylor Vaughan. The clinic may be considered at the present time as an outgrowth of the Vaughan Graham Clinic, which was established jointly by Dr Vaughan and Dr William Randolph Graham. Dr John Warlick Thomas recently became associated with the clinic.

WASHINGTON

Medical Society Dedicates Bulletin to Doctors Hospital—The King County Medical Society designated its November 20 Bulletin the Doctors Hospital issue in honor of the recent completion of the hospital. The bulletin contains historical material and illustrations of the new unit as well as a history of the King County Medical Service Corporation. Doctors Hospital according to the bulletin, represents a "milepost in the life journey" of the King County Medical Society. The approximate cost of one million dollars included an allocation of \$665,000 by the FWA. The remainder was provided by the medical service corporation (*THE JOURNAL*, Dec 18, 1943, p 1059 and Nov 25, 1944, p 847).

WEST VIRGINIA

Changes in Health Officers—Drs Allen E LeHew, Lewisburg and James R Richardson Union, have been appointed part time health officers for Greenbrier and Monroe counties, respectively, succeeding Dr Herbert Duncan, former district health officer, who is now in Nashville, Tenn.—Dr Garnett P Morison, Charles Town, has been appointed as part time health officer of Berkeley County, to succeed Dr Henry R Dupuy, Martinsburg.

GENERAL

Social Hygiene Day—February 7 has been announced by the American Social Hygiene Association as National Social Hygiene Day. Special educational observances will be held throughout the country.

Federation for Clinical Research—Investigators wishing to present papers before the Southern section of the American Federation for Clinical Research in Dallas some time in January are instructed to send abstracts of not more than 200 words to the chairman, Dr Alfred W Harris, 1719 Pacific Avenue, Dallas 1, by January 1. The Southern section is planning a two day meeting, the exact dates for which have not yet been announced.

Injuries in Coal Mines—Final figures on injuries in coal mines in the United States in 1942, the first full calendar year of American participation in the war, reveal that accident frequency rates that year were the lowest since 1930 and that production of coal per man hour of work was the highest in the nation's history according to the Bureau of Mines, Department of the Interior. Compilations by the accident analysis division show that 530,861 men were employed in anthracite and bituminous mines in 1942, a decline of 15,831 from 1941. These employees produced a record total of 640,000,000 tons of which 582,000,000 came from the bituminous fields and 58,000,000 from the anthracite region of Pennsylvania. To produce this quantity of coal, 1,471 men lost their lives and 69,564 men suffered non-fatal injuries that disabled them for more than the remainder of the day on which the accident occurred, the bureau reported in a publication analyzing accidents for 1942. Assuming a uniform payment of \$5,000 for each fatality and \$100 for each nonfatal accident the bureau estimated that injuries cost the nation about \$14,311,400 in compensation payments. Chief causes of accidents in both bituminous and anthracite mines were falls of roof, first, and haulage (transportation), second. Proving that fatalities can be prevented in coal mines, 6,201 of the 6,940 bituminous mines listed in the bureau's compilation worked through 1942 without a death.

Association for Research in Nervous and Mental Disease—The twenty-fifth annual meeting of the Association for Research in Nervous and Mental Disease will be held at the Waldorf-Astoria Hotel, New York, December 15-16, under the presidency of Col Franklin G Ebaugh, M C Among the speakers will be

Dr John C Whitehorn Baltimore Changing Concepts of Psychoneurosis in Relation to Military Psychiatry
Lieut Col Malcolm J Farrell and Major Norman Q Brill M C Neurotic Reactions in Psychopaths
Lieut Col Roy R Crinker M C A Dynamic Study of War Neuroses in Fliers Returned to the United States
Drs Edward A Strecker and Kenneth E Appel Philadelphia, Psychiatry Contrasts in the Two World Wars
Brigadier John R Rees British Army Development of Psychiatry in the British Army
Brig Gen Eugen I C Reinartz Research Aspects at the AAM School of Aviation Medicine in Nervous and Mental Diseases
Major Gen George B Chisholm Canadian Army Psychological Problems of Demobilization
Col William C Menninger M C Problem of the Discharged Neuro-psychiatric Patient
Capt Lewis L Robbins M C Mental Hygiene Unit, Army Air Forces
Major Fred F Sencer Jr M C An Experimental Unit for the Retraining of Psychoneurotic Soldiers
Lieut Col Guy C Randall and Major Harry C Blair M C and Dr Jack R Ewart Eastern Psychiatric Reactions of Patients with Amputations
Capt David G Wright M C Anxiety Related to Aerial Combat
Major Ivan C Berlien and Lieut Col Frederick R Hanson M C Psychiatry in the Combat Division
Lieut Col Ralph T Collins M C Neuropsychiatry with an Overseas Evacuation Hospital
Lieut Comdr Herbert I Harris (MC) Importance of the Emotional Outlet in Psychotherapy
Lieut Comdr Howard I Rome (MC) Psychopathology and Group Therapy
Comdr George A Rimes, Lieut Comdr Leslie B Hohman and Lieut Comdr Lawrence C Kolb (MC) Methods of Recovery in Combat Fatigue and the Influence of Therapy
Lieut Manuel M Pearson and Lieut Comdr Robert A Cohen (MC) Psychotherapy in a Naval Convalescent Hospital
Drs Lawrence S Kubie and Sydney G Margolin New York Therapeutic Role of Drugs in the Processes of Repression Dissociation and Synthesis
Capt Ephraim Roseman M C Electroencephalography and Head Injury
Major George M Haas M C Head Injuries in Aircraft Accidents
Major Frank H Mayfield and Capt John W Devine Jr M C Causalgia
Drs Lewis J Pollock James G Colseth and Alex J Arief Chicago Electrodiagnosis of Peripheral Nerve Lesions
Major Herman B Snow M C Psychiatric Procedure at the Rehabilitation Center Second Service Command
Lieut Col Walter E Britton, M C Convalescent Reconditioning Program for Neuropsychiatric Casualties in the U S Army
Col John H Baird M C Neuropsychiatric Problems of the Veterans Administration
Dean A Clark senior surgeon U S Public Health Service Reserve and Victor H Vogel surgeon U S Public Health Service Mental Illness and the Expanded Federal State Vocational Rehabilitation Program
Dr Leonard E Himler, Ann Arbor Mich Psychiatric Rehabilitation in Industry

Additional Grants for Physical Medicine—A new group of seven grants aggregating \$185,000 has been announced by the Baruch Committee on Physical Medicine. The new grants include \$50,000 to the Massachusetts Institute of Technology, Cambridge, Mass. \$40,000 to the University of Minnesota Medical School Minneapolis \$30,000 to Harvard Medical School, Boston \$30,000 to the University of Southern California School of Medicine, Los Angeles \$15,000 to the State University of Iowa College of Medicine, Iowa City, \$15,000 to the University of Illinois College of Medicine Chicago, and \$5,000 to Marquette University School of Medicine Milwaukee. The grants to the Massachusetts Institute of Technology and the University of Minnesota are in addition to the gift of \$1,100,000 made by Mr Baruch in April, at which time grants were made to Columbia University College of Physicians and Surgeons, New York University College of Medicine the Medical College of Virginia, Richmond, and for minor research and fellowship programs for the advancement of physical medicine. The present gift to the Massachusetts Institute of Technology is in support of a five year program of training and research in electronics, instrumentation and physics in relation to medicine to be carried on under the auspices of the department of biology and biologic engineering. It was the conviction of the scientific advisory committee of the Baruch Committee on Physical Medicine that Baruch Fellows and other physicians should have more than a superficial knowledge of the physics and technology underlying the physical methods and instrumentation used in this field and it was suggested that training in this aspect might effectively be centered at the Massachusetts Institute of Technology. The program will be under the general supervision of Francis O Schmitt, Ph D head of the department of biology and biologic engineering and under immediate supervision of Kurt S Lion D Eng, assistant professor of applied biophysics who is an expert in physical instrumentation. The

grant of \$40,000 to the University of Minnesota is to support the development of a three year teaching and fellowship program in physical medicine. The primary objective of the program is to be the furtherance of fundamental training of research workers and teachers. The program has as its basis the development of scientists in the field of physical medicine. As an auxiliary to this basic training facilities will be developed for the training of clinicians and technicians. The other grants have been allocated from the fund of \$200,000 given by Mr Baruch in April. The sum of \$30,000 was granted to Harvard Medical School for establishment of a three year program to provide fellowship or residencies to be used for the benefit of qualified physicians who are selected to be trained in this field. This sum will be administered by a strong standing committee on physical medicine recently appointed by Dr C Sidney Burwell, dean of the Harvard Medical School composed of Drs James B Aver, Derek E Denny-Brown William T Green, James H Means Arthur L Watkins and Eugene M Landis chairman. Appointment to the fellowships which generally carry stipends of \$2,500 will be made annually but may be renewed to provide up to three years of specialized study and research. Emphasis will be placed on training a few men in basic research and clinical investigation. Unusual opportunities for clinical experience and research in the psychologic and psychiatric aspects of physical medicine will be available at Harvard. The first year will be wholly or in part devoted to basic research related to physical medicine in one of the preclinical sciences such as physiology, anatomy or biochemistry. The second year will be spent in clinical training in physical medicine at the Massachusetts General Hospital and other hospitals affiliated with the Harvard Medical School. In the third year, fellows will be assistants in physical medicine with clinical responsibilities. For candidates with extensive previous training, one year clinical fellowships will also be granted. Applicants must have an M D degree from an approved medical school and a minimum of one year of internship in an approved hospital. Applications may be obtained from the Dean Harvard Medical School, 25 Shattuck Street Boston 15. The sum of \$30,000 is granted to the University of Southern California to inaugurate a program of teaching and research in physical medicine in its medical school. The sum of \$15,000 is granted to the University of Illinois to inaugurate a teaching program in physical medicine at its medical school. The sum of \$15,000 is granted to the University of Iowa to assist in a joint research and teaching program concerning the effectiveness of different methods of applying heat to the deep tissues of the human body. Finally, the sum of \$5,000 is granted to Marquette University for continuance of research in the physiology and pathology of nerves and muscles as related to physical medicine. In discussing these grants Dr Frank H Krusen, director of the Baruch Committee pointed out that Mr Baruch had been particularly interested in the important field of electronics as applied to medicine and he said that the center at the Massachusetts Institute of Technology gave promise of revolutionizing the application of electronics in the diagnosis and treatment of the sick. Dr Krusen announced that the administrative board of the Baruch Committee does not contemplate the recommendation of any further large grants for the establishment of additional departments of physical medicine in our medical schools. Main attention will now be directed to the adequate development of the centers already established and to providing advice in the organization of proper teaching of physical medicine in medical schools and through the committee on war and postwar physical rehabilitation and reconditioning, an attempt would be made to promote proper development of physical medicine in the rehabilitation and reconditioning of both military and civilian casualties of war.

CORRECTION

Digitalis Poisoning—In the article by Herrmann et al which appeared in the November 18 issue of THE JOURNAL, table 2 is a duplication of table 1 table 3 should be table 2 and the following table was omitted

Social Insurance and Family Allowances

The social insurance scheme of the government, which affects the life of every person from the cradle to the grave, has been unanimously approved in the House of Commons. Mr Butler, minister of education, moved that the House 'welcome the intention to establish an enlarged and unified system of social insurance and a system of family allowances.' He said that the various schemes for social betterment expressed the universal desire for a more closely knit society, in which all shared together both the risks and the opportunities. They seemed to concentrate more on the younger generation and on children and also to insist that in the interest of the country and the workers the government must push ahead with the policy of full employment. Every child should be guaranteed the best possible basis of physical health, but it was difficult to calculate or guarantee the nature of the benefits which the child received. The system of family allowances, he said, was intended to help the general economy of the family and was not intended to be based on any question of subsistence. The family was expected to maintain the first child, he explained, because the family should continue to have responsibilities of its own, especially in regard to the first child, and because its inclusion in the benefits would more than double the cost of the scheme. The real argument for family allowances, he said, was that they helped a family to stand the strain where it was felt most. He had been asked whether or not family allowances would raise the birth rate. That was not the government's sole reason for introducing them, he answered, but it hoped that an increase would result. The plan would give greater confidence to our families.

Regarding assistance in kind the provision of meals and milk had already been established on a large scale, but the government's view was that this policy must now be carried to its logical conclusion. In spite of war difficulties the number of children taking their midday meal at school had risen from 300,000 to 1,600,000. But there was a long way to go before all children got their meals at school, the minister stated. The government had decided that when the immediate urgency for house repairing in London was finished school meals should be given an equal priority with the other most urgent needs of the country. School milk could be made free at the same time cash allowances were introduced. School meals on this scale were something new in our social system, he pointed out, giving all children a 'fair start' physically.

Children under 5 years old had been regarded as a gap in the government's policy, Mr Butler stated. The national milk scheme and the provision of welfare foods—orange juice, cod liver oil, and so forth—which was an important part of the war-time plan, would be continued for a while. There was no country in the world, he said, which had been able to introduce such a vast program of social reform as we had done and at the same time defeat one of the greatest tyrants in history.

Few voices of criticism have been heard against this vast system of social insurance and family allowances. Even the conservative *Times* gives the scheme unqualified support in its editorials. Endorsing the government White Paper, it declares that the scheme is a concrete expression of the solidarity and unity which in war have been the nation's bulwarks against aggression and in peace will be its guaranty of success in the fight against individual want and misfortune. The *Times* also endorses the government's decision not to allow any group in

the community to claim exception from insurance. Those who by reason of their own superior security are not willing to share the risks of all are described as claiming the right, which cannot be admitted, to "make a separate peace with want."

Professor Ernest W Hey Groves

The death of Professor Hey Groves, at the age of 72 years, has removed a prominent figure in British surgery. He began his medical life as a general practitioner but soon became interested in surgery. He obtained the Fellowship of the Royal College of Surgeons and was appointed to the surgical staff of the Bristol General Hospital. He also became senior demonstrator in anatomy at Bristol University. A mechanical turn of mind led him to specialize in orthopedics, and he invented numerous orthopedic splints and devices. Before the introduction of the Smith-Petersen nail he worked at improving the operative treatment of fractures of the neck of the femur by fashioning pins of beef bone and of the horn of the stag and the rhinoceros. In 1913 he advocated the fixation of fractures by steel pins passed through the bone and attached to outside supports. This required only the use of a drill instead of the more complicated plating then in general use. His work in the last great war increased his reputation, and in 1915 he produced a primer on 'Gunshot Injuries of Bones.' Other successful works from his pen were his "Synopsis of Surgery" (1908), "Modern Methods of Treating Fractures" and "Surgical Operations." He was president of the British Orthopedic Association in 1928-1929 and of the Association of Surgeons of Great Britain and Ireland in 1929-1930. He edited the *British Journal of Surgery* from its inception in 1913 throughout almost its whole career of preeminence in surgical literature, until advancing years compelled him to resign in 1941. His guidance played a large part in its success.

Sheltered Employment for the Disabled

Sir Godfrey Ince, director general of man power, has stated in a speech at Manchester that a company controlled and financed by the Ministry of Labor is to be formed to provide sheltered employment for severely disabled persons who cannot hold their own in competitive industry. It was unlikely that the whole employment of the disabled could be dealt with by voluntary organizations, the director stated. The special company and any voluntary organization receiving assistance from the Ministry of Labor must be required to apply its profits, if any, to promoting these objects, it was explained, and will be prohibited from paying any dividend to its members.

The Editorship of the Lancet

The proprietors of the *Lancet* have announced with much regret the retirement of Dr Egbert Morland from the editorial chair. He joined the staff of the *Lancet* in 1915 and has been editor since 1937. He has well sustained the reputation of the journal as both a scientific and a political organ of the profession. The Royal College of Physicians and the Royal College of Surgeons have shown their appreciation of his work by admitting him to their fellowship. He is succeeded by Dr T F Fox, who has been for some years assistant editor. He will be assisted by Dr E Clayton-Jones.

Oil Cargo Under Red Cross Flag

After the British submarine *Unruly* had engaged an enemy ship with gunfire which caused the crew to abandon ship, it is reported, the submarine drew nearer and it was then seen that the enemy vessel was flying a Red Cross flag and had red crosses on her bow. The commanding officer of the submarine, Lieut J P Tyfe, decided to examine her before sinking her. He found that she was not so innocent as she looked. Her cargo consisted of oil in drums and the Nazi ensign was found under the captain's pillow. As she was clearly a supply ship,

she was blown up. Such abuse of the Red Cross was perhaps to be expected, many times during the war the Germans have shown no respect for either the Red Cross or the Geneva Convention, to which they are signatories, by attacking and sinking hospital ships plainly marked as such and by killing medical staff, nurses and patients.

Whiter Bread

One of the measures adopted by the government to insure a sufficient supply of food for all was to enforce an 85 per cent extraction of the national flour from wheat. A new order has been made decreasing the rate of extraction to 82.5 per cent. The object is stated to be to improve the national bread. The new flour will produce a whiter and better quality loaf, with no appreciable loss of nutritional value.

BUENOS AIRES

Oct 11, 1944

Medical Care and Social Insurance

Dr. Jose Arce of Buenos Aires recently lectured before an audience at the Centro de Estudiantes de Medicina on medical care and social insurance. More than 60 per cent of the Argentine population have an income of less than \$1,200 a year, he said. Families with such incomes have a right to free medical care by the state, he thought. He also recommended a large department for medical assistance, with branches in several provinces. The members of the department would supervise the work of family physicians, hospitals and centers of social medical care. A large number of additional hospital beds are necessary, according to Dr. Arce, 84,000 beds to be given free of any charge to people in need of social aid, 42,000 beds to be given to patients belonging to families with incomes of from \$1,250 to \$3,000 and 14,000 for patients who can pay a reasonable amount. It is advisable to establish medical councils and hospital councils to supervise the medical and hospital work in the country, he added.

Thyroid and Metathyroid Diabetes

Dr. Bernardo A. Houssay of Buenos Aires, president of the Argentine Society of Biology, and Dr. Oscar Orias, also of Buenos Aires, recently lectured before the society. According to Houssay, prolonged administration of thyroid does not cause diabetes in normal dogs, whereas it does cause the disease in dogs with normal glycemia and a pancreas experimentally reduced to 25 or 23 Gm. The animals are more susceptible to the disease when they are treated by administration of thyroid or preparations of the anterior lobe of the hypophysis before the administration of thyroid. The disease may be of the thyroid type, which lasts only during administration of thyroid extract, or of the metathyroid type, which persists even after discontinuation of the thyroid treatment.

Dr. Orias reported the results of experiments on normal and partially pancreatectomized rats. Subtotal pancreatectomized rats which conserve 5 per cent of pancreatic tissue tolerate the first diabetogenic dose of alloxan better than normal rats. The latter tolerate repeated subthreshold doses of alloxan with intervals of ten days between the injections, whereas subtotally pancreatectomized rats develop diabetes with relatively small doses of alloxan.

Medical Care in Boarding Schools

A law was recently passed by the executive government under which the heads of boarding schools are compelled to give attention to the physical and mental development of the children in the schools. The law provides that schools shall have clinical departments with a physician and a nurse, proper preventive and curative dental care will be given to the children, they will have four daily meals, which will be prepared in accordance

with dietetic standards of the National Department of Public Health. Infractions will be punished by closing the offending schools.

Cultivation of Digitalis

Digitalis purpurea grows as a native plant in several regions of Argentina. Up to now, several pharmacists have taken the plant free of any cost for preparation of the pharmaceutical product for sale. The government is now in charge of the preservation and cultivation of the plant on a large scale. Free use of the plant is forbidden. The seeds of the plant hereafter will be harvested by the government and distributed to pharmacists.

Clinics for Heart Diseases

A polyclinic for heart diseases was recently opened to the public as a department of the Faculty of Medicine of the University of Buenos Aires. The building was constructed and properly equipped with a donation of \$62,000 from the Virgilio F. Grego foundation. The foundation will contribute \$10,200 a year to the support of the polyclinic. The University of Buenos Aires will also provide funds for expenses.

Brief Items

Dr. Enrique A. Boero, gynecologist of Buenos Aires, former professor of gynecology and obstetrics of the Faculty of Medicine of Buenos Aires and an active worker in social medicine, died recently at the age of 64 years.—Dr. Arturo Mo, a well known psychiatrist of Buenos Aires, died recently at the age of 62 years.

The General Department of Penal Institutions of Argentina is negotiating with the government to increase the amount of money allowed for food in prisons.

The date of celebration of the second Pan American Congress of Ophthalmology was postponed from November 1944 to November 1945. The congress will be held in Montevideo. Pan American ophthalmologists are requested to send the annual dues to insure uninterrupted reception of the journal *Ophthalmologia Ibero Americana*, which is the official organ of the congress.

Dr. Juan Carlos Llames Massini, professor of obstetrics of the Faculty of Medicine of Buenos Aires, died recently in Buenos Aires.

Marriages

WILLIAM L. AINSWORTH, Bay Springs, Miss. to Miss Dorothy Alford of Crystal Springs in Charlottesville, Va. September 1.

JOSEPH PEDEN BAILEY to Miss Louise King Howe, both of Rock Hill, S. C., in Flat Rock, N. C., September 16.

JAMES NELSON HADDOCK, Cape Girardeau, Mo., to Miss Dorothy Mae Vaughan in Toledo, Ohio, June 8.

THOMAS DOYLE GHENT, Lancaster, S. C., to Miss Lydia Epps of Kingstree in Summerville, September 15.

JOHN EDWARD GILLICK, Clayton, N. Y. to Miss Ruth Catherine McGovern of New York, October 14.

JAMES YOUNG GRIGGS, Asheville, N. C., to Miss Betty Lee DeBusk in Winston-Salem, September 26.

THOMAS S. BROWNELL, Cleveland, to Miss Mary Miller of Mogadore, Ohio, in Akron, October 7.

GORDON L. NEIGH JR., Grand Island, Neb., to Dr. ROSALIE EVA BREUER of Lincoln, September 28.

EDWARD C. WOLSTON, Springfield, Mass., to Miss Maxine L. Askey of Oil City, Pa., September 28.

COSME JOSE FERRAIOLI, Santurce, Puerto Rico, to Miss Marjorie Whelan of New York recently.

LEROY B. DENNIS JR., Florence, S. C., to Miss Mary Emily Hinnant of Columbia, October 21.

LESTER J. CANDELA, Brooklyn, to Miss Margaret O'Keefe of Litchfield, Minn., recently.

JOHN MASSEY COBB, Tuskegee, Ala., to Miss Octavia Sadler of Birmingham, October 24.

Deaths

Charles Morton Rosenthal * Brooklyn, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore 1934 fellow of the American College of Surgeons member of the Brooklyn Ophthalmological Society, specialist certified by the American Board of Otolaryngology, assistant ophthalmologist at the Long Island College Hospital and clinical assistant ophthalmologist at the dispensary and senior clinical assistant ophthalmologist at the Brooklyn Eye and Ear Hospital died in the New York Post-Graduate Medical School and Hospital New York, September 1, aged 35 of subacute bacterial endocarditis

Griffin Anderson Allen, Boston Meharry Medical College Nashville Tenn 1913 died August 5, aged 68, of arteriosclerotic heart disease and obesity

Max Bacharach, Maryland, N Y Julius-Maximilians-Universität Medizinische Fakultät, Würzburg Bavaria, Germany 1920 died September 12 aged 49, of chronic nephritis

James Reginald Bailey * Keysville Va., Medical College of Virginia Richmond 1926 on the associate staff of the Southside Community Hospital, Farmville, died September 13 aged 43

William Thomas Barnette, Springfield Ky, Kentucky School of Medicine Louisville, 1900, died in Shelbyville September 23 aged 70

Thompson Mitchell Berry, Baton Rouge, La., Medical Department of Tulane University of Louisiana, New Orleans 1908 died in Our Lady of the Lake Sanitarium September 20 aged 65

Howard Black * Palo Alto Calif, Starling Medical College Columbus Ohio 1896 member of the Pacific Coast Ophthalmological Society died September 21, aged 70, of heart disease and generalized arteriosclerosis

Jacob Peter Bottenhorn, Sigel, Pa., Ohio Medical University Columbus 1904 died in the Warren State Hospital Warren July 12 aged 66 of carcinoma of the prostate

Harry Maxwell Box * Coral Gables Fla, Miami Medical College Cincinnati, 1907, member of the Ohio State Medical Association fellow of the American College of Surgeons for many years practiced in Cincinnati where he had been police and fire surgeon and on the staff of the Deaconess Hospital died September 30, aged 60 of coronary heart disease

William Gerald Brymer, Bandera Texas College of Physicians and Surgeons Dallas 1905 also a pharmacist, past president of the Medina-Uvalde-Maverick-Val Verde-Edwards-Real Kinney-Terrell-Zavala Counties Medical Society served on the staff of the Santa Rosa Hospital, San Antonio while practicing in Dewar Okla served as chief surgeon of the Consolidated Fuel Company examiner for the Selective Service System member of the Lions Club, died August 12, aged 72 of heart disease

Thomas Henry Burke, Pittsburgh Georgetown University School of Medicine Washington D C 1929, served an internship at the Pittsburgh Hospital, died July 2, aged 49 of coronary occlusion

Arthur Alphonsus Chenay, Washington D C Detroit College of Medicine 1897 veteran of the Spanish-American War and World War I medical consultant for the National Rehabilitation Committee of the American Legion for many years died September 17 aged 68 of coronary artery disease

Lucie A Hemenway Cook, Bloomington Calif Northwestern University Woman's Medical School, Chicago, 1897 died September 25, aged 74

Walter C Crysler * Littleton Colo, Harvey Medical College, Chicago 1901 for many years county physician served as mayor of Littleton on the staffs of the Mercy Hospital and the Porter Sanitarium and Hospital where he died August 4 aged 74 of coronary thrombosis

Grant W Curless, Beloit Wis Atlanta College of Physicians and Surgeons 1900 served during World War I died August 27, aged 69 of coronary heart disease

Bernard Charles Dorset, La Crosse, Wis., University of Pennsylvania Department of Medicine, Philadelphia 1904 served during World War I, formerly practiced medicine in Denver where he had been on the staffs of the Children's St Luke's Presbyterian Denver General Colorado General and St. Joseph's hospitals, died November 1, aged 67, of coronary thrombosis and diabetes mellitus

George G Fitz, Bancroft Idaho State University of Iowa College of Medicine Iowa City 1898 member of the American

Medical Association served as vice president of the Pocatello Medical Society, served during World War I, died in Salt Lake City, September 25, aged 72, of cerebral hemorrhage

Ralsa Marshall Fuller, Greenwood, S C, University of Georgia Medical Department, Augusta, 1899 member of the American Medical Association, served during World War I, died at the Greenwood Hospital September 28 aged 68

Everett Rush Gose, Fayette, Mo Barnes Medical College St Louis, 1907, died August 21, aged 63, of heart disease

Homer Wilford Gough, San Antonio Texas, University of Texas School of Medicine, Galveston 1915, member of the American Medical Association, at one time on the staff of the Southwestern Insane Asylum, died September 21 aged 62 of heart disease

Charles A Hadsell, Alamosa, Colo Missouri Medical College, St Louis, 1885, associate member of the Colorado State Medical Society honorary member of the Alamosa County Medical Society, died September 3, aged 90 of myocarditis

Sherman Blaine Hibbard, Kansas City Mo Rush Medical College, Chicago 1912 member of the American Medical Association died in Rochester, Minn September 21, aged 56 of general peritonitis and leiomyoma of the stomach

Robert Samuel Jacobs * Washington D C, Medical College of Virginia, Richmond 1930, died in the Laurel Sanitarium Laurel Md, July 12 aged 39

Harry Charles Kendig * Mount Joy Pa Jefferson Medical College of Philadelphia 1930, served an internship at the Washington Hospital, Washington member of the Rotary Club died September 20, aged 41

Cornelius C Kepler, Pocahontas, Iowa Chicago College of Medicine and Surgery, 1913, died September 3 aged 55, of carcinoma of the prostate

Jesse Arthur King * Elaine, Ark University of Arkansas School of Medicine Little Rock, 1918, medical director of the Elaine Hospital, surgeon for the Missouri Pacific Railroad died in Monterey, La, August 7, aged 57, of pulmonary tuberculosis

Robert Harrison Kistler * Lansford Pa, University of Pennsylvania School of Medicine, Philadelphia 1915 served during World War I, at one time chief surgeon for the Lehigh Coal and Navigation Company formerly on the staffs of the Pennsylvania and Wills hospitals in Philadelphia member of the police commission and a director of the First National Bank died in the Coaldale State Hospital, Coaldale, October 4 aged 55

William Russell Lightbody, Manchester, N H Harvard Medical School Boston 1910 died in Boston August 11, aged 62 of cerebral arteriosclerosis

William W Livingston, Dunlo Pa, Eclectic Medical Institute Cincinnati 1902 member of the American Medical Association served as a lieutenant in the medical corps of the U S Army during World War I medical inspector in his school district for many years died September 2, aged 72 of heart disease

Frank William Maier, Medical Lake Wash Beaumont Hospital Medical College, St. Louis 1892 member of the American Medical Association, formerly health officer of Rocky Ford Colo resident physician, Eastern State Custodial School, where he died August 16, aged 79, of coronary heart disease

Jerome C Malone, Faunsdale, Ala Memphis (Tenn) Hospital Medical College, 1901 member of the American Medical Association died September 26, aged 66 of heart disease

Charles N Martin, Warren Ark., Medical Department of Tulane University of Louisiana New Orleans 1878, member of the American Medical Association died September 7, aged 89 of senility and hiccups

George Scott Martin * Susanville Calif, University of Louisville Medical Department Louisville, Ky 1909 a major in the medical corps of the U S Army serving in France and England during World War I member of the American Association of Industrial Physicians and Surgeons physician and surgeon for the Southern Pacific Railroad city health officer past president of the Rotary Club formerly medical director and owner of the Riverside Hospital died October 8 aged 57 of coronary occlusion

Edgar Stanley Matthews, Bunkie La Medical Department of Tulane University of Louisiana, New Orleans 1900 served as secretary and treasurer of the Avoyelles Parish Medical Society for eight years mayor of Bunkie formerly a member of the state board of health local surgeon for the

Texas and Pacific Railway, died September 25, aged 71, of arteriosclerosis and bronchopneumonia

Leon Jordan May, Anna, Ill Kentucky School of Medicine, Louisville, 1905, member of the American Medical Association, since July 1941 managing officer of the Anna State Hospital, died September 22, aged 68, of coronary occlusion

Bernard William Meyer, Columbus, Ohio, Ohio Medical University Columbus, 1897, died August 11, aged 80

John Thomas Mize, Wallis, Texas University of Nashville (Tenn) Medical Department, 1898, while practicing in Bryan served as county health officer, died September 22 aged 72, of tumor of the lung

Guilford Dudley Mottier, Patriot, Ind Miami Medical College, Cincinnati, 1900 died in the Good Samaritan Hospital, Cincinnati, September 28, aged 71, of coronary disease

Hans P Nielson, Des Moines Iowa, Ensworth Medical College, St Joseph, Mo, 1899, died September 25, aged 67 of hypertensive heart disease

Ludwig John Oblazney, Simpson, Pa, Jefferson Medical College of Philadelphia 1935, member of the American Medical Association, served an internship at the Allentown Hospital, Allentown, on the staff of St Joseph's Hospital, Carbondale where he died August 15, aged 35, of acute dilatation of the heart

Charles Palen, Dubuque, Iowa, Northwestern University Medical School, Chicago, 1902, died September 30 aged 65 of pulmonary edema

Jacob Allen Patton, Los Angeles Rush Medical College, Chicago 1890 retired in 1933 as medical director and second vice president of the Prudential Life Insurance Company Newark, N J, after thirty-eight years of service formerly vice president and president of the Association of Life Insurance Medical Directors, assistant professor of chemistry materia medica and genitourinary surgery at his alma mater from 1893 to 1908, died September 25, aged 77 of heart disease

William Otto Pauli @ Cincinnati, Johns Hopkins University School of Medicine, Baltimore, 1907 a member of the medical staff of the Union Central Life Insurance Company since 1910, serving as assistant medical director from 1911 to February 1942, when he was elected associate medical director at one time demonstrator in clinical microscopy at the Medical College of Ohio died September 16, aged 62

Robert Lee Payne, Monroe N C, Medical Department of Tulane University of Louisiana, New Orleans 1911, served during World War I died September 7, aged 57 of coronary occlusion

Samuel Edward Peden, Perryville, Mo, Barnes Medical College, St Louis 1910 served during World War I died in the Veterans Administration Facility, Jefferson Barracks, September 2, aged 63, of generalized arteriosclerosis and cerebral thrombosis with left hemiplegia

C P Perkins, Batesville Miss Louisville Medical College, Louisville, Ky, 1903, died in St Joseph's Hospital, Memphis, Tenn October 9, aged 67, of ruptured gastric ulcer

Doctor Absalom Pettit, Vicksburg Miss Medical Department of Tulane University of Louisiana New Orleans 1906 member of the American Medical Association, died September 21, aged 60

Norman W Phillips @ Clear Lake, Iowa State University of Iowa College of Medicine, Iowa City, 1887 an affiliate Fellow of the American Medical Association served as health officer, died September 10, aged 85, of cardiovascular renal disease

Harry Pomerantz @ Lancaster Pa, Medico-Chirurgical College of Philadelphia 1909, attached to British Expeditionary Force during World War I on the staffs of the Rossmore Sanatorium, St Joseph's Hospital and the Lancaster General Hospital where he died September 19, aged 57, of carcinoma of the stomach

Alfred R Poole, Milan, Mo, Kentucky School of Medicine Louisville, Ky, 1904 died September 3 aged 66, of chronic glomerulonephritis

Frances Mary Preston-Brown, Los Angeles Woman's Medical College of Pennsylvania Philadelphia 1941 served an internship at the Hospital of the Woman's Medical College of Pennsylvania Philadelphia, and a residency in psychiatry at the New York State Psychiatric Institute and Hospital in New York died suddenly August 18 aged 40

John Robert Priest Jr, Houston, Miss, University of Tennessee College of Medicine Memphis 1937 member of the American Medical Association formerly health director of Kemper, Clarke and Wayne counties served an internship at the Morningside Hospital in Tulsa, Okla, and the City Hospital in Mobile Ala, died October 4, aged 32, of acute cardiac failure

Gideon D Quinn, Springfield, Mo, Louisville Medical College Louisville, Ky, 1896, died in South Bend, Ind September 24 aged 76 of cerebral hemorrhage

Robert Ramroth, Marion, Ohio, Western Reserve University Medical Department, Cleveland, 1895, member of the American Medical Association, died in the Mount Carmel Hospital, Columbus September 2 aged 72 of adenocarcinoma of the ascending colon and coronary occlusion

Howard Jarvis Reger, Vernon, Texas, Fort Worth School of Medicine Medical Department of Fort Worth University, 1902, member of the American Medical Association died July 26 aged 74, of arteriosclerosis

Conrad B Rice, Louisa Ky, Hospital College of Medicine, Louisville, Ky 1898 member of the American Medical Association served as president and member of the board of directors of the Bank of Blaine died in a hospital at Cincinnati, September 25 aged 70, of pneumonia

PUBLIC HEALTH SERVICE

William Smith Bean @ Medical Director, U S Public Health Service, Washington, D C, University of Virginia Department of Medicine, Charlottesville, 1914, interned at the U S Marine Hospital, Baltimore, commissioned in the regular corps of the public health service in August 1915 served as medical officer on the Coast Guard Cutter *Androscoggin* and with Dr Joseph Goldberger on pellagra investigations in cotton mill villages in South Carolina during World War I did extracantonment work in that state, with the exception of a few temporary assignments had devoted twenty years to the operation of U S Marine hospitals, served as executive officer of the Marine hospitals in New Orleans, New York City and Ellis Island, medical officer in charge of the Marine hospitals at Mobile, Ala Pittsburgh Norfolk, Va, and Baltimore, from June 1944 until his death he was chief of the Hospital Division, Bureau of Medical Services, died suddenly November 26 aged 54, of coronary thrombosis

Edward Cranch Ernst @ Medical Director U S Public Health Service, Washington, D C Columbia University College of Physicians and Surgeons, New York 1911, served an internship at the Southern Pacific Railroad Company Hospital in San Francisco commissioned on Jan 10, 1916, as assistant surgeon in the U S Public Health Service and immediately assigned to duty at the

Marine Hospital in San Francisco during 1917 served as medical officer on the U S Coast Guard Cutter *Baer* served at the San Francisco Quarantine Station in 1918 and later for three years in the Philippine Islands where he gained considerable experience in smallpox, cholera and leprosy, serving as medical officer in charge of the San Lazaro Contagious Disease Hospital in Manila and as extracantonment officer for the Philippine National Guard, in 1921 was detailed to the Division of Industrial Hygiene in Washington, D C, and New York City for twelve years, beginning in February 1922 served as medical director to the U S Employees Compensation Commission in 1934 appointed assistant chief of the division of personnel and accounts at headquarters of the public health service, in 1938 at the request of Dr Hugh S Cumming, director, was made assistant director of the Pan American Sanitary Bureau, a position he had held at the time of his death and in which he traveled widely in Central and South America, working closely with Latin American health authorities in cooperative programs for the improvement of health conditions, member of the Royal Tropical Medical Society American Public Health Association, Far Eastern Tropical Medicine Association Association of Military Surgeons of the United States and the American Hospital Association died suddenly November 3 aged 58 of coronary occlusion

Joseph Esthner Robinson, Memphis, Tenn., Memphis Hospital Medical College, 1911, member of the American Medical Association served during World War I formerly on the staff of the United States Marine Hospital died September 28, aged 58, of coronary thrombosis

Joseph William Robinson ⊕ Lisbon, Ohio, Eclectic Medical College, Cincinnati, 1927, served during World War I, died September 21, aged 50

James Alfred Rolfs Jr., Washington D C, University of Michigan Medical School, Ann Arbor, 1923, member of the American Medical Association, died October 5 aged 45

Eli W Rose, Hundred, W Va College of Physicians and Surgeons, Baltimore 1888, died September 29, aged 80

Frank M Rumsey, Conneautville, Pa Cleveland Homeopathic Medical College 1903 died in the Meadville City Hospital, Meadville, July 8, aged 70, of carcinoma of the prostate and myocarditis

Presley Bliss Russell, Carthage Miss, Memphis (Tenn) Hospital Medical College, 1901, died in the Mississippi Baptist Hospital at Jackson September 25, aged 65

Olaf Halvard Rystad, Grand Forks, N D Chicago College of Medicine and Surgery, 1913, member of the American Medical Association, on the staff of the Deaconess Hospital

Charles William Schery ⊕ St Louis, St Louis College of Physicians and Surgeons, 1904 formerly assistant to chair of histology, pathology and bacteriology at his alma mater, for many years city pathologist and bacteriologist died in the Lutheran Hospital, September 9, aged 67, of generalized carcinomatosis

Stuart Harris Sheldon ⊕ Portland, Ore, Rush Medical College, Chicago, 1902, fellow of the American College of Surgeons served during World War I, chief, obstetric service, Salvation Army White Shield Home, on the staff of the Emanuel Hospital, where he died August 26, aged 68, of coronary thrombosis

Frank Morton Sherman ⊕ Newton Mass Harvard Medical School, Boston, 1881 an Affiliate Fellow of the American Medical Association, died September 14, aged 87, of cerebral hemorrhage

Henry Connelly Shurtleff, Philadelphia University of Pennsylvania Department of Medicine, Philadelphia 1888, died in the Presbyterian Hospital, July 23, aged 80, of arteriosclerosis and diabetes mellitus

Mark Harrison Smith ⊕ Glendale, Calif, State University of Iowa College of Homeopathic Medicine, Iowa City, 1895 Rush Medical College, Chicago, 1898, died September 8, aged 73

CAPT ROY E BAZE M C,
A U S 1910 1944

CAPT JOHN S WILLIAMS M C,
A U S, 1909 1944

LIEUT HAROLD B THORNBURG (MC),
U S Navy, 1911-1944

died at Lake Plantaganet, Bemidji, Minn., August 16 aged 68 of coronary thrombosis

Abraham S Sanders, Brooklyn Denver and Gross College of Medicine 1903 member of the American Medical Association formerly on the staffs of the New York Post Graduate Mount Sinai St Marks and People's hospitals all in New York died in the Queens General Hospital, Jamaica, July 28 aged 66 of heart disease

Samuel Reasin Wallis, Armour S D College of Physicians and Surgeons Boston, 1900, member of the American Medical Association county coroner, died August 30 aged 76 of heart disease

Maria Constantine Walsh, Philadelphia, Woman's Medical College of Pennsylvania Philadelphia, 1893 member of the American Medical Association died in the Jefferson Hospital July 1 aged 80, of auricular fibrillation and arteriosclerosis

KILLED IN ACTION

Roy Ellis Baze, Chickasha Okla University of Oklahoma School of Medicine Oklahoma City 1936 member of the American Medical Association, served an internship at the Hamot Hospital in Erie Pa commissioned a first lieutenant in the medical corps of the Army of the United States on April 9, 1942 later promoted to captain served in the African campaign before going to southern France where he parachuted into occupied territory awarded the purple heart posthumously, killed in action in France August 24 aged 34

John Scott Williams Ridgway, Pa Jefferson Medical College of Philadelphia, 1935 member of the American Medical Association served an internship at the Methodist Episcopal Hospital in Philadelphia and the Burlington County Hospital Mount Holly N J commissioned a

first lieutenant in the medical corps Army of the United States on May 12 1942, later promoted to captain awarded the Bronze Star Medal on July 26, killed in action in France August 14, aged 34

Harold Babcock Thornburg ⊕ Lieutenant (VC) U S Navy Hollywood Calif, University of Southern California School of Medicine Los Angeles, 1942 served an internship at the Naval Hospital Bremerton Wash commissioned a lieutenant (jg) in the medical corps of the U S Navy on July 5 1942 was assigned to a South Pacific squadron after his completion of flight surgeon training in Pensacola Fla promoted to lieutenant on May 1, 1943 killed in action at sea in the South Pacific area September 21 aged 33

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated DDNJ and foods, FNJ. The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Alterative Tonic Compound—Hale Drug Company Birmingham Ala. Shipped Jan 7 1942. Composition essentially methenamine potassium iodide a compound of iron strychnine (0.01 grain per fluid ounce) extracts of plant drugs including a laxative and an alkaloid bearing one with alcohol sugar and water. Misbranded because label falsely represented that product was an efficacious alterative tonic as well as a treatment for irritations caused by impurities of the blood and would aid in the proper functioning of the bowels kidney and bladder. Also misbranded because fabricated from two or more ingredients whereas label failed to declare common or usual names of these or the quantity of strychnine present.—[DDNJ FDC 809 December 1943]

Bi Lets—Bi Lets Inc Nashville Tenn. Shipped March 10 1942. Composition essentially colamel aloë and bile. Misbranded because though a laxative it was not labeled with the warning that it should not be taken in cases of nausea vomiting abdominal pain or other symptoms of appendicitis and further label failed to warn that frequent or continued use might result in dependence on laxatives.—[DDNJ FDC 810 December 1943]

Blue Ridge Mountain Mineral—Robert T Sides trading as the C S & W Mineral Company Kannapolis N C. Shipped Feb 21 1941. Composition a natural mineral which when prepared according to directions on label consisted essentially of a dilute solution of ferric sulfate with minute amounts of sulfates of other minerals and some ferric hydroxide in suspension. Misbranded because label falsely represented that it was an effective treatment for high blood pressure pellagra nervous indigestion rheumatism kidney bladder and stomach disorders hemorrhoids blood poison female complaints and many other things.—[DDNJ FDC 823 December 1943]

Bowel Regulator—Hale Drug Company Birmingham Ala. Shipped Jan 7 1942. Composition essentially compounds of sodium potassium magnesium and iron tartrates carbonates and extracts of plant drugs including a laxative and an alkaloid bearing drug with sugar and water. Misbranded because label failed to give adequate directions for use of this product as a laxative and the directions given provided for no limitation as to duration of use. Further misbranded because labels failed to warn adequately that a laxative should not be taken in cases of nausea vomiting abdominal pain or other symptoms of appendicitis and that frequent or continued use might result in dependence on laxatives to move the bowels. Further misbranded because label falsely represented that product would efficaciously regulate bowels and stomach and neutralize in acid condition of the body. Misbranded again because fabricated from two or more ingredients whereas label failed to state common or usual names of said ingredients. Misbranded finally because label failed to bear accurate statement of quantity of contents.—[DDNJ FDC 809 December 1943]

Cos Tal Big C—Alvin M Hitt trading as Cos Tal Laboratories Company Savannah Ga. Shipped Oct 7 1941. Composition an aqueous emulsion containing volatile oils including oil of sandalwood and resins. Misbranded in that the label statement "Big C is indicated in cases of unnatural discharges" was false and misleading in representing that the product would be efficacious in the cure mitigation treatment or prevention of unnatural discharges whereas it would not.—[DDNJ FDC 825, December 1943]

Malitrate F I—W Warren Walters and Organic Laboratories Inc, Los Angeles. Shipped Dec 8 1941. Composition concentrated apple juice. Misbranded because labels represented that the product was efficacious in the cure mitigation treatment and prevention of disease by reason of the alkalinizing properties of its components that it was of value in preventing or treating gastrointestinal disorders intestinal toxemia diarrhea various forms of nausea and a good many other things.—[DDNJ FDC 827 December 1943]

Special Formula 833—Brewer & Company Inc Worcester Mass. Shipped June 15 1941. Composition shown by biologic examination to contain approximately 1 milligram (333 International units) of vitamin B₁ (thiamin chloride) per tablet. Misbranded because of misleading label representation that the product would constitute an adequate or effective treatment for vitamin B deficiency which might cause constipation loss of vigor various nervous and other important symptoms or would be of special value for elderly men and women as claimed.—[DDNJ FDC 784 September 1943]

A COMPREHENSIVE BLOOD EXAMINATION FOR CLINIC ROUTINE

To the Editor—Physicians working in general medicine in busy public clinics can be aided considerably by having in hand at the first visit of the patient as much routine laboratory data as is practicable. At the New York Dispensary we have found it possible, with small cost in time and effort, to determine the hemoglobin, the plasma protein and the erythrocyte sedimentation rate at the first visit of new patients by utilizing a portion of the blood withdrawn for the Wassermann test and employing the new density technic for hemoglobin and plasma protein and a concurrent sedimentation rate determination. The density method was devised last year by Dr Phillips and others at the Rockefeller Institute for Medical Research. Devised especially for the use of medical units in our armed forces, it has proved to be admirably adapted for use in busy civilian clinics. It is accurate, requires the minimum of time and skill and calls for no special apparatus. The method as yet has not been described by its authors, but a description can be found in Peters and Van Slyke's "Quantitative Clinical Chemistry—Methods," 1943 edition, and in Kolmer's "Clinical Diagnosis by Laboratory Methods," 1944 revised edition.

For clinic use I have found the following plan satisfactory. The new patient, except in trivial cases, is sent from the admission interview direct to the nurse who collects blood for the Wassermann test. An extra 3 cc of blood is withdrawn and placed in a 10 cc vial charged with oxalate. The examination is then made by the nurse or the specimen is sent to the laboratory or to the consulting room of the physician. The examination is so easy that the physician himself can complete it without serious interruption of his clinical work. The final step in the examination is made at the end of one hour, or after a half hour if approximate results are sufficient.

This comprehensive blood examination at the first visit has definite advantages. There is less psychologic resistance on the part of the patient than is occasioned by the Wassermann test alone, for he is told that the examination is for general information about his blood. But the chief advantage is that the results obtained indicate to the clinician at the first visit many of the cases of concealed infection or of anemia and thus aid him suitably to apportion his time between the more and the less serious cases.

FREDERICK H HOWARD M.D., New York

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Revocation of License for Performance of Nontherapeutic Abortions—After notice and hearing the State Board of Health of Mississippi revoked Johnson's license to practice medicine in Mississippi on the ground that he had procured an abortion not necessary to preserve the life of a pregnant woman which is a cause for the revocation of a license under the Mississippi medical practice act. The physician, by a writ of certiorari brought the matter for review before the circuit court, Hinds County, which reversed the order of the board and remanded the cause for further proceedings. The board then appealed to the Supreme Court of Mississippi.

The physician contended first that the proceedings by which his license was ordered revoked by the board were not lawfully initiated. He argued that the state board of health took no action itself prior to the hearing that the alleged notice served on him was initiated solely by the executive officer of the board without the authority of the board and that since no charge against him had been lodged with the board the proceedings instituted were unauthorized and illegal. The notice of the proceedings served on the physician, said the court was in the form of a registered letter and was signed by the secretary and executive officer of the board, had attached thereto the seal of the board and notified the physician to appear before the board at the time and place named therein for a hearing on the charges therein set out. The notice purported to be sent by the authority and direction of an order of the executive committee of the board adopted at a called meeting Oct 6 1943, at which only two of the members of the committee were present the order reciting that certain complaints and grievances against the physician had been made known to the committee. The state board of health continued the court by statute, consists of ten members. Nine of those members are appointed by the governor, eight to be licensed physicians and one to be a licensed dentist. The tenth member apparently, is elected and is to be the executive officer and secretary of the board and is vested with all the authority of the board when it is not in session. The physician who signed the notice served on Johnson was the duly elected member of the board who lawfully was the executive officer and the secretary of the board. By statute the board is also authorized to appoint an executive committee of three members and, as stated in the statute

Said executive committee shall have authority to execute all the powers herein vested in said board in the interim of the meetings of said board and any action of said executive committee shall be legal and binding until modified or annulled by said board of health.

Any two members of the executive committee shall be a quorum for the transaction of business. (Code 1942 Section 7027)

Further said the court, by Section 8893, supra the board "may on its own initiative or on complaint suspend or revoke for any cause named below [including the cause alleged as the basis for the action against Johnson] any license of a physician licensed to practice in Mississippi. Thus it is seen that the executive committee can legally act through two of its members, that the action of that committee and the issuance of the notice to Johnson were the valid acts of the board itself and that no complaint formal or otherwise, to either the board or the committee is essential to the lawful initiation of the proceedings by the board.

The physician next contended that the notice of the charges given him in the proceedings was not legally sufficient in substance in that the charges set out in the notice were vague, general indefinite and inconsistent and did not inform him of the nature and cause thereof so that he could prepare his defense, thus denying him his constitutional right of due process of law. The notice answered the court served on Johnson described the charges against him as "Procuring or attempting to procure, or pretending to procure an abortion that is not necessary to preserve the life of a pregnant woman." This was in the exact

language of the statute (Section 8893 (a) (5), supra) and the wording of the order of the executive committee authorizing and directing its issuance. Following the receipt of this notice by Johnson his counsel wrote the board requesting that he be furnished with the cause and nature of the accusation. In reply counsel for the board wrote Johnson's counsel, giving him the names of ten women on whom "unnecessary abortions" had been procured by Johnson with the approximate times when such acts were performed. Construing the original notice and this letter together, they charged, in the last analysis, that Johnson, at different times approximately stated, had procured abortions on ten named pregnant women, which abortions were not necessary to preserve their lives. This eliminated the alternatives of attempting or pretending to procure or aiding or abetting in procuring such abortions set out in the original notice. Was this sufficient to give the physician notice of the nature and cause of the offense? Mississippi has no statute prescribing the form and substance of such notices. The statute does define the offense, as previously noted, and the original notice here was in the words of the statute which itself is usually sufficient, even in criminal charges. However, the essentials of such notices, in the absence of statutes prescribing them, seem well settled. As was said by the Supreme Court of Florida in *State v Whitman* 116 Fla 196 150 So 136

And in such proceedings it is sufficient if the accused is informed with reasonable certainty of the nature and cause of the accusation against him has reasonable opportunity to defend against attempted proof of such charges and the proceedings are conducted in a fair and impartial manner free from any just suspicion or prejudice unfairness, fraud or oppression.

Further as stated in 41 Am Jur 184 "In the absence of statute requiring it, the strict rules of pleading in judicial cases do not apply to revocation proceedings before a board of medical examiners." It is recognized that the members of an administrative board such as a board of health or board of medical examiners are not learned in the law and legal proceedings and more laxity is allowed in their pleading and procedure than in strict law courts provided that no substantive rights of the accused are denied him.

The accusation in this case, continued the court, informed the physician of every element involved in the charge except that it did not describe the means, nor technique used in producing the abortions, or undertake to give a definition thereof. It was not necessary to set out the means. Lacking lawful justification for the act, it mattered not whether it was done by giving medicine or using instruments—it was abortion. Nor was it material that the notice failed to define abortion. As was said in 1 Am Jur 133 "In criminal law the crime of abortion is the wilful bringing about of an abortion without justification or excuse." The only justification or excuse in this case would have been the necessity to save the lives of the women concerned. The charge says that was not necessary. Stripped of all technical niceties, and looked at in a common sense way, it would seem rather absurd to inform a physician that he had performed abortions not necessary to save the lives of the women and at the same time to assume that he did not know the meaning of the word abortion and that he needed to be given a definition and a description of the detailed manner in which an abortion is produced. It is significant that the physician after receiving the additional information requested by his counsel proceeded with the hearing and without requesting further particulars, which, in civil actions, precludes such person from thereafter complaining as to a lack of knowledge of details. While this court is zealous to guard individual rights and would caution quasi-judicial tribunals to be careful that such rights are fully protected in proceedings before them, yet it is clear in this case that the physician was informed with reasonable certainty of the nature and cause of the accusation against him, had ample opportunity to defend against them and had a fair and impartial hearing.

The court accordingly, reversed the judgment of the trial court and ordered reinstatement of the judgment or order of the state board of health revoking Johnson's license to practice—*Mississippi State Board of Health v Johnson*, 19 So (2d) 445 (Miss., 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Results Obtained with Vaccine of Killed Tubercle Bacilli.—Wells and his associates report studies on the protective effect of heat killed tubercle bacilli against human tuberculosis conducted in the Mental Hospital, Kingston, Jamaica, over a period of more than ten years. The average annual patient population of the Kingston Mental Hospital approximated 2,500, with about 540 admissions each year. The number of patients dying from all causes per year averaged 260, and approximately 25 per cent of all deaths were due to tuberculosis. Among 434 persons with tuberculosis under observation during the study, only 61 (14 per cent) had clinical tuberculosis on admission; the remainder developed it while in the institution. Patients were permitted access to large compounds, one for each sex, where practically no restrictions were placed on their freedom of movement. The effect on the spread of tuberculosis of an arrangement of this kind in a population with a high incidence of open tuberculosis is apparent. Certainly the conditions presented a severe test for studies to determine the protective value of inoculations with a heat killed tubercle bacillus vaccine. The authors found significantly lower tuberculosis attack and death rates among recipients of heat killed tubercle bacilli administered intracutaneous than among persons alternately

chosen but not vaccinated, who served as controls. The differences were greatest during the first two years of observation. The attack and death rates for tuberculosis among persons strongly positive to tuberculin on admission to an institution with a high tuberculosis prevalence were consistently and significantly lower than such rates in groups of persons containing weak and negative tuberculin reactors, vaccinated or controls. The results obtained in this study support the suggestion that there is a practical use for this or a similar heat killed tubercle bacillus vaccine in certain groups of individuals who may be subjected to unusual risk of tuberculous infection. Such groups might include medical students, pupil nurses, hospital attendants, household contacts and possibly others.

Diagnosis of Hemorrhage in Man.—Shenkin and his associates found that after operations in which much blood was lost some patients showed none of the signs ordinarily expected after profuse hemorrhage. They made observations on 18 volunteers who were bled approximately 500 cc and on 17 who were bled about a liter. Estimations of pulse rate, blood pressure, venous pressure, cardiac output (ballistocardiograms) and hematocrit were made before and after the hemorrhage, during the recovery and often after replacement of the blood. Cardiac output diminished little after the loss of 500 cc of blood; after the loss of a liter it regularly diminished significantly and during syncopal attacks it diminished profoundly. After completion of the bleeding, the cardiac output slowly returned toward the value found before the hemorrhage. The effects of hemorrhage on healthy men may be divided into three stages of severity. In the first stage the subject is symptom free at rest and has a pulse rate and blood pressure within normal limits. On arising, acceleration of pulse rate and some diminution of blood pressure are found. In the second stage there are still no noteworthy abnormalities as long as the subject is recumbent and at rest, but the upright position cannot be tolerated and syncope soon overwhelms the subject if he arises. In the third stage syncopal attacks accompanied by bradycardia occur even though the subject is at rest and recumbent. The old concept that acute hemorrhage can be readily diagnosed by a rapid pulse and a low blood pressure is erroneous. Recumbent subjects may be bled to the point of collapse without exhibiting conspicuous tachycardia, and during the period of severe symptoms profound bradycardia is the rule. The blood pressure usually remains within the normal range until the symptoms of collapse begin, when it diminishes profoundly. Hemorrhages causing no signs or symptoms as long as the subjects are recumbent can be detected by having them sit or stand upright.

Effect of Restriction of Activity on Recovery of Rats from Myocardial Injury.—Thomas and Harrison say that, although rest in bed is the most widely used method of treatment of patients with acute myocardial disorders, there have been practically no well controlled clinical or experimental studies concerning its value and its limitations. Opinions vary widely about the length of time during which rest should be applied as well as regarding the strictness of the regimen of rest. The effect of exercise on animals with acute myocardial injury has been studied previously, but experimental attempt

at enforcing rest on animals has not heretofore been attempted. The authors review observations on a large number of rats in which experimental injury was produced by application to from three to five areas on the left ventricular surface of the head of a nail heated almost to redness. The mortality of these rats was decidedly greater when the animals were kept closely confined in small cages which restrict muscular activity. Animals so confined display considerably less activity, as measured by the work adder method than control animals allowed to wander freely about in larger cages. Observations with the optional treadmill have shown that following injury to the heart the rat tends to return to the preoperative level of exercise within a period of three to seven days. Enforced strenuous muscular effort even when carried out within twenty-four hours after cardiac injury did not materially increase the mortality in rats. Likewise such exercise carried out three or more days after the operation did not cause a significant increase in mortality. The authors point out that prolonged rest in bed following myocardial infarction in patients has serious disadvantages as well as some advantages. On the basis of the available evidence it would appear that during the first two weeks the advantages of strict bed rest probably outweigh the disadvantages but that after this time the reverse is probably true.

Alloxan Diabetes in Rabbits.—The Baileys and Hagan report pathologic findings in the pancreas and other organs of rabbits at varying intervals after the intravenous injection of alloxan. A single injection of a 5 per cent aqueous solution of alloxan was used. The total diabetogenic dosage was 200 mg of alloxan per kilogram of body weight. Smaller doses were used for the production of transitory diabetes. Lesions induced by alloxan in the islets of Langerhans of the rabbit begin almost immediately after the injection and are degenerative from the beginning. Degenerative changes in the islet cells are already apparent in the initial hyperglycemic stages, while in the hypoglycemic stage they progress to a point where they approach those of the diabetic phase. The pancreatic acini remain normal throughout, and changes in organs other than the pancreas are minimal. The most striking characteristic of the lesion is its specificity for the islets of Langerhans. The beta cells are affected most severely while a certain percentage of the alpha cells remain intact. From the point of view of the investigator it is unfortunate that the alpha cells are not completely destroyed. There are conspicuous species differences in the extent of extrapancreatic lesions induced by the injection of alloxan. The lesions of the kidney in the rat are much more severe than those in the rabbit. The lesions induced by small doses of alloxan are very striking. They resemble more the sequences produced in other organs following administration of certain carcinogenic hydrocarbons than the lesions produced by massive doses of alloxan or those recognized in human diabetes. Injection of alloxan not only provides a useful technic for obtaining diabetic animals in the laboratory and for the study of diabetic complications but also provides a useful technic for the study of numerous problems in general pathology.

Experimental Chronic Carbon Monoxide Poisoning of Dogs.—The U S Department of Labor sets the limit of safe concentration of carbon monoxide in air in industrial plants at 0.01 volume per cent (100 parts per million). Lewey and Drabkin state that the amount of carbon monoxide combined with hemoglobin varies greatly even with the same exposure. A person exposed continually for some months to the same carbon monoxide concentration in air may, supposedly by adaptation show a gradual decrease in the percentage of carbon monoxide hemoglobin. Hence safety limits given in terms of carbon monoxide concentration in air give only an approximate idea of the toxicity relationships of the gas in the body. The value of 0.01 volume per cent carbon monoxide in air leads theoretically in man to approximately 16 per cent carbon monoxide hemoglobin. By agreement of the safety engineers of the U S Army the upper permissible limit is set at 20 per cent carbon monoxide hemoglobin. Dogs exposed for five and one-half hours a day, six days a week, over eleven weeks, to an atmosphere containing 0.01 volume per cent of carbon monoxide and reaching daily 20.1 ± 1.1 per cent of carbon monoxide hemoglobin showed a consistent disturbance of postural and position reflexes and of gait. Some of them showed a pathologic electrocardiogram characteristic of anoxia and necrosis of single heart muscle

fibers. Their central nervous systems showed, three months after termination of the experiment, microscopic changes in the cortex and white matter of the cerebral hemispheres, in the globus pallidus and in the brain stem. These alterations corresponded in type and localization to those found in acute carbon monoxide poisoning but were smaller, more scattered and less destructive. They followed in their arrangement the course of the blood vessels, the walls of which were only occasionally damaged. One dog, in which the posterior coronary artery had been ligated one year prior to the exposure for a period of only eighteen days to carbon monoxide, showed the earliest and severest cardiac and cerebral changes of all animals. This suggests that an inadequately functioning heart increases the general risk in carbon monoxide poisoning and may be responsible for a higher degree of brain damage. Chronic carbon monoxide intoxication may occur in dogs at carbon monoxide concentrations which have been regarded as within the safety limits for man. These experiments do not permit conclusions about potential human reactions to the same conditions.

Work in Heat as Affected by Intake of Water, Salt and Glucose.—Pitts and his collaborators investigated the effects of water, salt, glucose and water soluble vitamins on 6 healthy fully acclimatized young men. The best performance of fully acclimatized young men on a good diet, performing intermittent hard work in the heat, was achieved by replacing hour by hour the water lost in sweat. Considerably less than this amount of water led in a few hours to a serious inefficiency and eventually to exhaustion. The replacement of salt hour by hour had no advantage. Replacement of salt loss meal by meal was adequate. Administration of glucose proved of little or no value when compared with the great benefit of large amounts of water. There was no advantage from administering 200 mg of ascorbic acid 20 mg of thiamine hydrochloride, 20 mg of riboflavin or large doses of brewers' yeast, either singly or together either during work or the day before. Water transport and supply are sometimes difficult but when water is available it should not be forbidden on the traditional ground that during work it is bad for one. Men should be encouraged to drink to capacity. When a good daily diet is not available because of failure of supply or is not eaten because of ignorance or anorexia, which is so common in hot environments, it is desirable to ensure adequate intake at least of salt, by means of salted drinking water or tablets and probably of vitamins by means of concentrates.

Epidemic of Bacillary Dysentery—Kinnaman and Beelman describe an epidemic of bacillary dysentery that occurred in Newton, a town with a population of 11 000 in southeastern Kansas. Samples taken from the deep wells showed no contamination, but those from various points on the distribution system were heavily contaminated. A bit of information which proved of extreme importance was received from a Santa Fe Railway water department employee who said that a sewer block had occurred at a Mexican village on the southwest outskirts of the city about the time that dysentery cases developed in the city. Contrary to previous statements by city officials that no change had been made to the distribution system further information uncovered the fact that changes had been made on the two main supply lines entering the city at a point close to this Mexican village. Investigation showed that a service connection came from a main to the Mexican villages. The situation was reconstructed as follows. When the water pressure was off on September 7 and 8, persons in the village attempting to get water apparently opened the valves and, not obtaining water, left them open, this in turn allowed the sewage backed up in the box to flow through the drain opening into the water main. The epidemiologic investigation revealed that the peak onset occurred on September 10 with 743 persons giving this date as the beginning of their sickness. As a result of the epidemic, business in the city was practically at a standstill on Thursday, September 10, when it is estimated about 2,000 persons were ill. Laboratory examination showed the predominating organism recovered from the stools of sick persons and from the intestinal mucosa in fatal cases to have been *Shigella paradysenteriae*, Flexner group. The water supply of Newton also supplies all passenger coaches of the Santa Fe Railroad. There were 2,871 regular passenger cars (Pullman and coaches) supplied with water between the dates of September 3 and the afternoon of September 14. From scattered cases traceable to Newton, it is assumed that there were many cases other than those occurring in the city. A great number of war workers were absent from their jobs for several days, an unknown number of soldiers and civilians were infected, the ordinary business of the city was disrupted for three days. Later, important transcontinental trains many of them troop trains were delayed an average of one hour while taking water at a nearby safe supply. With institution of proper public health protection measures the epidemic quickly subsided.

Immunization Against Influenza—Recent evidence on the effect of subcutaneous vaccination with influenza virus showed that the incidence of epidemic influenza was consistently reduced by about 75 per cent when the period between vaccination and an epidemic was short. Hirst and his associates present studies on a similar vaccine in which the period between vaccination and an epidemic was about one year. The PR8 strain of influenza A and the Lee strain of influenza B were used for the production of most of the vaccine. Penal institutions in five widely separated states of the Midwestern, Southern and Eastern United States were chosen for the study. These institutions offered obvious advantages for this type of work, since in each of the groups the medical care was good, there was adequate, readily available hospital space and there were full time physicians in attendance. Seven such institutions were studied. Administration to human beings of formaldehyde killed influenza virus, concentrated from allantoic fluid, resulted in a high order of antibody response within two weeks after injection. Even after one year the great majority of persons vaccinated had antibody levels considerably above their prevaccination titer for the PR8, Lee and a current 1943 strain. An investigation of the occurrence of epidemic influenza A in seven widely separated populations one year after vaccination of part of these groups showed that the attack rate among vaccinated persons was consistently lower than that of control individuals. The average reduction in the attack rate was of the order of 35 per cent.

Prophylactic Use of Sulfadiazine in Meningococcal Infection—Pamton states that approximately 18 000 men were given 2 Gm of sulfadiazine at 1 p m 2 Gm at 7 p m and 1 Gm at 7 a m each man receiving a total of 5 Gm in a

period of eighteen to nineteen hours. The only type of reaction noted was a skin eruption, which occurred in 6 cases. Up to eight weeks after the drug was ingested no man with meningococcal infection either meningococcemia or meningococcal meningitis, has been hospitalized since the first day the drug was administered, no case of scarlet fever has been diagnosed since the prophylactic administration of sulfadiazine. The incidence of upper respiratory infection was reduced by approximately 50 per cent for nine days following the administration of the drug. The incidence of contagious virus infection, as measles and mumps, was also reduced for one week following the ingestion of the drug. The results cannot be explained by better climatic conditions. The number of men appearing on sick call was reduced by approximately 33½ per cent for a period of eleven days following the ingestion of the drug.

Stab Wound in the Right Ventricle—A soldier was stabbed in the left chest with a pocket knife. Two hours after the injury Gillesby found the patient cyanotic, cold and clammy. His pulse was barely perceptible and his blood pressure unobtainable. All superficial veins were distended. Cheyne-Stokes respiration was present. Heart sounds were muffled, and the apex beat could not be located. Physical findings revealed left pneumothorax. A diagnosis of cardiac tamponade and left pneumothorax was made. An incision was made over the sixth rib from the scapular line to the costochondral junction. The rib was exposed and subperiosteal resection planned. However, because the anesthetist stated that she could no longer feel a pulse, an intercostal incision was rapidly made and the ribs were separated manually. The lung was pushed aside and the pericardium palpated. A faint pulsation could be felt. The pericardium was widely incised, releasing a gush of clots. The heart began to beat violently, and blood could be seen coming from an incision in the right ventricle. A finger was placed on the hole and an apical suture applied. The time consumed from the beginning of the incision to this point was about two minutes. The pulse was better. The wound in the heart was closed with two silk sutures so placed as to avoid the coronary vessels. Bleeding was well controlled. The pericardial sac was cleaned of clots and the heart inspected. The extensive transpleural approach used is advocated as an "all purpose" incision. Hyperventilation was used to prevent pulmonary complications. The pericardium was left open in communication with the left pleural cavity to permit effusion to drain into the pleural cavity. Electrocardiographic tracings taken postoperatively showed only an inversion of the T wave in lead 4.

Rabies—Palik and Moss present an analysis of 12,237 patients admitted to the Pasteur Institute Clinic in New Orleans and of 3,003 animal brains submitted for examination and diagnosis during the period from Jan. 1, 1934 to Oct. 31, 1943 inclusive. The Pasteur treatment was given to 4,146 patients. Of 3,003 animal brains submitted for examination 1,003 or 43.3 per cent were positive for rabies. Stray dogs which were

unavailable for examination, were responsible for exposure to rabies in 45 per cent of the patients treated. New Orleans experienced an epidemic of rabies beginning in the latter part of 1936 and continuing until the latter part of 1939. The present epidemic began early in 1943 and has shown a higher human mortality than the previous epidemic. Dogs were responsible for the exposure of 90 per cent of the patients treated and for all of the seven deaths from rabies. Actual injury by a proved rabid animal increases the mortality rate. Injuries about the face, head or neck are more dangerous than are injuries to other parts of the body. Injuries through clothing are less dangerous than injuries inflicted through the bare skin. The mortality from rabies is greater in Negroes than in white patients. Mortality from delay in instituting treatment is not significantly increased until two weeks after the injury. Rabies can be controlled by controlling the dog population.

*Carotenemia. V. S. Caviness—p. 432

Carotenemia—According to Caviness, carotenemia is much more common than is indicated by the number of cases reported in the literature. He suggests that the condition is usually not recognized but is diagnosed as biliary jaundice. The chief differential points between jaundice and carotenemia are that: 1. There is no itching of the skin in carotenemia. 2. There is no yellowing of the scleras in carotenemia. 3. Yellowing of the skin in carotenemia is most intense in the palms and soles and about the nasolabial folds. In jaundice it is most intense in the scleras and on the trunk. 4. The urine in patients with jaundice is likely to show a deeper discoloration. 5. Urine chemical tests for bile should be positive in jaundice but negative in carotenemia. 6. In carotenemia there should be a high blood carotene level and no increase in the bilirubin content of blood, the blood bilirubin is high in jaundice. Icterus index changes, however, should be the same in the two conditions. 7. In carotenemia the stools are normal in color, in jaundice they are clay or putty colored. Cantarow and Trumper state that carotenemia occurs most commonly in children and diabetic patients, chiefly because of the prominent part that carotene containing vegetables occupy in their diet. Caviness reports the histories of 2 diabetic men who developed carotenemia. The first patient, a man aged 69 gave a history of having eaten large numbers of carrots daily. The second patient had lived for three weeks on a self prescribed diet of eggs. He was eating 27 eggs a day and was taking no other nourishment.

Orthopedic Aspects of Brucellosis. E. G. Chumard—p. 279
Use of Stilbestrol in Carcinoma of Prostate. C. D. Donahue—p. 284
Psychogenic Asthma. S. Mayer Jr.—p. 287

Brucellosis—Staub states that less than 10 per cent of the patients with the chronic form of brucellosis have fever. Brucellosis is an important public health problem. Improved state and federal laws are necessary in the control, marketing and distribution of dairy products. A closer fraternity can profitably be developed between the medical and veterinary professions in the control of brucellosis and of other human infections contractible from animals. The medical profession must realize the unbelievable prevalence of brucellosis. The author thinks that 10 per cent of the population have brucellosis but that only about 1 per cent of infected persons are detected and treated. The sulfonamides are almost without value, although some believe that succinylsulfathiazole can benefit cases presenting early intestinal involvement. Penicillin shows only mild laboratory success. Fever therapy is more beneficial in acute than in chronic cases, especially in refractory cases not responding to vaccine therapy. Antiserum treatment is usually restricted to acute, severe attacks or exacerbations. Vaccine therapy seems

most promising in the treatment of acute and chronic brucellosis. The author uses a vaccine made only from the abortus strain. He prefers deep muscular injections and avoids subcutaneous injections. Vitamin therapy is an important supportive measure, as is also iron and liver. Thiamine hydrochloride seems especially beneficial in stimulating the production of opsonins, as does likewise the intravenous injection of nicotinic acid. Pent-nucleotide and bone marrow are both used in cases of extreme leukopenia.

Infectious Mononucleosis and Jaundice—According to Boger infectious mononucleosis is a protean disease whose only constant feature is an increase in the mononuclear elements of the blood at some time during its course. Those cases which present a sore throat and glandular enlargement are regarded as most typical and are diagnosed most frequently. A 19 year old boy presented many unusual features which are seldom encountered in the same patient and the condition would undoubtedly have been erroneously diagnosed if a positive heterophile agglutination had not been obtained. Despite the gravity of the illness the treatment was purely symptomatic. The withholding of sulfonamide medication seems justified in the opinion of others, who have found that the sulfonamide drugs do no good in cases of infectious mononucleosis. The fever reached a height of 105.2 F. The authors think that the fever temperature accounted for the patient's amnesia for a week

of his hospitalization. The pertussis-like cough, which was so severe that it produced blood streaked sputum and hoarseness of the voice that has persisted for more than two months is a feature of the disease which has not been commonly observed. Jaundice in infectious mononucleosis has been noted a number of times, but the mechanism of its production needs further investigation. Twenty-seven cases of jaundice are cited from the literature. The reported case illustrates the closeness with which infectious mononucleosis can simulate typhoid. The significant differential point was the generalized lymphadenopathy, which was not evaluated properly by reason of its having been found two and a half months prior to the onset of any acute symptoms.

Vitamin K in Menorrhagia—Gubner and Ungerleider state that recent observations indicate that the liver is intimately concerned with the metabolism of the female sex hormones and there is evidence to suggest that disturbances in liver function may be a factor in the genesis of some of the disorders of menstruation. Failure of the estrogen inactivating function of the liver may be contributory in the genesis of menorrhagia. Prothrombin formation occurs in the liver, and the level of plasma prothrombin is a sensitive index of the integrity of hepatic function. Vitamin K is intimately concerned with prothrombin formation and its administration is indicated whenever prothrombin deficiency exists. Observation of striking improvement with vitamin K therapy in a case of severe menorrhagia with prothrombin deficiency led the authors to undertake an investigation of its therapeutic effect in a series of cases. Vitamin K was given to 43 patients with chronic dysmenorrhea and menorrhagia. No medication other than vitamin K was employed. The dosage varied slightly, averaging twenty 5 mg tablets taken over a period of five days. Medication was begun in most cases one or two days before the onset of menstruation or on the first day of the menses. In 8 of 12 cases with a history of prolonged menstrual flow lasting six days or longer the duration of flow was reduced by one day or more. In the other 4 it was unchanged. In several women in whom spotting continued for ten or twelve days the flow was shortened to a normal length of four or five days. Of the 26 women in whom the flow continued for five days or less the duration remained unchanged in 16, was abbreviated in 8 and was prolonged in 2. Twenty-six of the women studied usually had clots during menstruation. The clots disappeared or diminished in 16 cases, were unchanged in 8 cases and increased in 2 cases.

Nutrition in Convalescence and Rehabilitation—Spies and his associates state that persons with nutritive failure treated at Lakeside Hospital, Cleveland, had a deficient diet which was their only barrier to health and the ability to work. Unless something was done about the prevention of relapses in the treating of these chronically diseased persons, they continued to be dependent on their families or on social agencies. The authors report observations on 500 persons selected from a large group of patients who had recovered following treatment in the Nutrition Clinic. In most instances these patients gained strength promptly following nutritive therapy, but they were kept under close medical supervision until their health was restored and they were able to fulfill discharge requirements, the ability to do a full day's work every day. Precise diagnosis is the first step in shortening convalescence and hastening rehabilitation following nutritive failure. This is not easy, and no formula applies in every case. It is necessary to correlate the detailed information obtained from a nutrition history, laboratory determinations, physical examination and general medical history. The 500 persons rehabilitated or reconditioned included members of the armed forces and agricultural domestic and industrial workers. The following four principles of nutritive therapy are recommended for shortening convalescence and rehabilitating persons who are ill solely from malnutrition. 1 The diet should provide 4000 calories and should contain from 120 to 150 Gm of protein and should be rich in vitamins and minerals. 2 Basic therapy should provide thiamine, riboflavin, niacin, ascorbic acid orally. 3 Synthetic vitamins should be given orally or parenterally. 4 Natural B complex should be given in the form of brewers yeast or extract or rice bran extract and/or liver extract.

Myoblastoma—Howe and Warren report 10 cases of myoblastoma together with 44 cases collected by Klemperer and 104 additional cases collected from the literature. Myoblastoma is derived from embryonic myoblasts and may be distinguished from the rhabdomyoma group. Fifty-six per cent of the cases reviewed by the authors occurred in the upper respiratory and digestive tracts. Fifty-nine cases involved the tongue, and of these 3 were malignant. Eleven per cent of the total cases were malignant and of these only 3 showed proved metastases. The authors think that whenever a myoblastoma is reported to have (1) atypism of cells (2) excess mitotic figures (3) spindle cell or sarcomatous pattern or (4) local invasion it should be treated surgically as a malignant tumor until more is known of the nature of these growths especially if the patient is over 50 years of age. The degree of radiosensitivity and frequency of metastasis are as yet unknown. Both appear to be low. Tumors under the mucous membrane or the skin have a great tendency to be associated with hyperplasia and epidermoid carcinoma of the overlying epithelium.

Spool Cotton as Suture Material—Spool cotton was the only suture material used by Floyd and Brockbank in 1659 general surgical procedures. They believe that spool cotton is an excellent suture material for all types of general surgery including clean and contaminated wounds. It is technically more difficult to handle than catgut and is thus conducive to painstaking surgery. It possesses minimal foreign body danger. Induration serum accumulation and postoperative wound infections are minimal with cotton.

Osteomyelitis With and Without Chemotherapy—Kenney presents an analysis of the experiences of surgeons with 3176 cases of acute hematogenous osteomyelitis. The mortality before the advent of chemotherapy was 23 per cent on the average 46 per cent in the toxic cases and around 3 per cent in the nontoxic cases. After sulfonamide was used the mortality was 35 per cent. Previous to the use of sulfonamide early bone decompression was almost prohibited by the severe mortality. Yet early bone decompression yielded the best results from the standpoints of the later integrity of the bone and function of the limb. Neither incision down to the bone aspiration nor withholding operation either before or after the sulfonamides has given as satisfactory results as early bone decompression.

The new drugs, by controlling the initial septicemia and that which may follow operative intervention, have now allowed safe, early procedures. The sulfonamide drugs have not proved of value so far as the local pathologic process is concerned. One must still depend on operation for the best results.

Ligation of Aorta and Both Common Iliac Arteries for Aneurysm—Monahan says that Owings ligated the aorta of dogs in three stages three weeks apart and finally tied and severed the aorta. He was able in a small percentage of cases to have the animal survive in a normal state of health. His results encouraged Monahan to apply the same principle of gradual occlusion in a case of aneurysm of the aorta in the human being. Monahan occluded the aorta of a Negro aged 49 in stages by rubber bands proximal to an aneurysm with division of both common iliac arteries. The patient lived approximately five months from the time of the first ligation. Seven cases of aortic ligation are reviewed, 4 partial and 3 total. Of the 3 patients with total occlusions, 2 had collateral circulation established at the time of operation and the third had paralysis of the extremities following ligation and survived probably because of his youth. Occlusion of the lower abdominal aorta is feasible. Man will tolerate division of both common iliac arteries after ligation of the aorta. Cotton tape has been demonstrated as the least noxious material for ligation. It seems reasonable that ligation in stages with cotton tape, plus ligation of both iliac arteries should cure aneurysms of the lower abdominal aorta.

Physiochemical Disturbance in a Severe Burn—Ficarra and Naclerio made chemical analysis on a man aged 43 who sustained severe burns and who died on the tenth hospital day. The patient exhibited sodium chloride changes hypoproteinemia destruction of body protein, alterations in carbohydrate metabolism and hemoconcentration. The acidosis which usually accompanies the burn syndrome was absent. An unexpected alkalosis occurred following the administration of citrocarbonate on the fifth day after the burn. Emphasis is placed on a study of the blood chemistry on or about the fifth day. At this time a break in the biochemical harmony occurs. This discord is manifested in an elevation of the end products of nitrogen metabolism associated with a fall in serum proteins plasma sodium and blood chlorides. Of 16200 cc of fluids administered parenterally 6900 cc was of plasma and 3100 cc of whole blood. Death on the tenth day was attributed to adrenal exhaustion and renal failure. The major cause of death in burns has not been established satisfactorily. It is believed that a severely burned patient dies of physiologic exhaustion. Therefore a study of the organs involved in this disturbed physiology (liver kidneys and adrenals) will assist in the elucidation of the unknown lethal factor. The exhaustion of the organs may be the cause of death when after the second week the patient seems to be improving. During the third week the initial danger apparently has been overcome. The anxious surgeon considers the patient sufficiently improved for a skin graft. However, the disturbed chemistry has not been restored. In the presence of this metabolic discord the administration of an anesthetic plus the surgical procedure may be sufficient to cause death. The thought is advanced that repeated examinations of the blood are necessary guides to the intelligent management and treatment of the severely burned patient. Whenever possible the laboratory studies should include a daily erythrocyte count hemoglobin urinalysis and blood chemistry determinations (proteins sodium chlorides nonprotein nitrogen icterus index and carbon dioxide combining power).

Effect of Ligation on Infection of Patent Ductus Arteriosus—Tubbs states that the persistently patent ductus differs from that found at birth in being relatively shorter. It may have no length at all and be of the so-called window type. The frequency of complicating subacute bacterial infection is unknown. In the past the prognosis after the supervention of infection has been fatal with exceedingly few exceptions, the duration of life after the onset of infection varying from one month to two years. Nine cases of subacute bacterial endarteritis complicating a patent ductus and treated by ligation are described, 6 of these patients are well today, from fifteen months to over four years after the operation. The effect of ligation on infection of a patent ductus has been dramatic. Infection must now be considered an absolute and urgent indication for operation. It is important that the supervention of infection should be diagnosed early, any patient with a patent ductus who has an unexplained fever for more than two weeks should be suspected of this complication.

Treatment of Burns and Wounds by Envelope Method—Osborne reports observations with this method in patients admitted to the plastic surgery and jaw injury service of the Stoke Mandeville Hospital. The 31 cases treated fall into three groups: 6 cases of new burns, 12 cases of old burns and 13 cases of unhealed wounds with loss of skin. The author used the tie on type of Bunyan-Stannard envelope. Application is done under gas and oxygen or some other form of light anesthesia. The previous dressings are removed and a smear is taken for bacteriologic examination. Under a continuous stream of 1 per cent electrolytic sodium hypochlorite in tap water 1-5 at 110 F the wound is cleansed with gauze swabs. All loose sloughs and destroyed soft tissue are removed. The area should be oozing blood at the end of ten to fifteen minutes after 5 to 8 pints has been used for a limb. Then a sterilized envelope sufficiently large to allow free movement of the limb is applied. The same solution is used for irrigating through the inlet, 5 pints being used for a limb. The solution is allowed to escape from the outlet as fast as it runs in so as to get the maximum chemical and mechanical effect. The envelope is allowed to drain for five to ten minutes. The interior of the envelope is dried by means of air blown through a sterile cotton wool filter by an electric hair drier or an electric suction machine. Adhesive seals are applied to the outlets and inlets. Subsequent irrigations are carried out without anesthesia three or four times a day. Several case histories are given. Envelope therapy provides a reliable method of treating burns and wounds with full thickness skin loss. The method seems ideal for eliminating the hemolytic streptococcus and for reducing risk of cross infection to a minimum. Two other striking features have been the dramatic improvement of the general condition and the maintenance of full function.

Intraperitoneal Chemotherapy—Gardiner believes that sulfapyridine possesses advantages over other sulfonamides for intraperitoneal use. He has used sulfapyridine in all stages of acute appendicitis over the past two and a half years and the

results have been gratifying. Seemingly hopeless cases of general peritonitis have resulted in rapid recovery, and many less advanced cases have done extremely well. Exudate was either reduced to a thin serous yellow discharge which did not last long or, if purulent, did not continue long. The author recommends the use of a fluid suspension, a solution not being possible owing to low solubility. The suspension is best made by rapidly stirring the finely powdered drug into sterile isotonic solution of sodium chloride. For 10 to 15 Gm of powder about 6 to 8 ounces of the sterile fluid is necessary. The thin emulsion is best squirted rapidly into the peritoneal cavity with a 10 or 20 cc record syringe. This method facilitates absorption and obviates adhesions. In the absence of pus or gross inflammation small doses suffice and 10 Gm in 4 ounces of saline solution is adequate. The author generally uses 15 Gm of sulfapyridine in 6 ounces of saline solution in contaminated cases. In cases with frank suppuration the author has inserted 25 Gm of sulfapyridine with no toxic results. The complications, which are often troublesome when the drug is given by mouth or injection, have been entirely absent. Sulfapyridine shows the slowest absorption rate and the lowest toxicity of any of the sulfonamides so far employed for intraperitoneal use. Contaminated wounds treated with an emulsion of the sulfonamide powders will heal by first intention in the large majority of cases. Intraperitoneal chemotherapy should now be included in the armamentarium of all emergency surgeons.

*Heparin in Intravenous Infusions Including Penicillin Therapy P Martin—p 308

Heparin in Intravenous Infusions Employing Penicillin—Martin has recently used heparin in all infusions of blood (fresh or stored) plasma and solutions of crystalloids. The heparin is added to the infusing fluid by injecting it through the cork of the bottle by means of a hypodermic syringe. The amount used has been 1 unit per cubic centimeter of fluid—equivalent to 1 cc of heparin per liter. Between 50 and 60 patients have received heparinized intravenous therapy. There has been no tendency to a recurrence of hemorrhage, and in postoperative cases there has been no evidence of bruising or hemorrhage in the area of the operation scar. In 8 cases the coagulation time was estimated before infusion and immediately afterward. In no case was there any significant alteration. It is suggested that heparin should be of value in preventing the thrombosis and phlebitis which are frequently seen when penicillin is given by intravenous drip. The impure solution of penicillin available at present irritates the endothelium of veins, causing phlebitis and a subsequent thrombosis. The author has in several cases employed heparin with penicillin. At first he used 1 unit of heparin per cubic centimeter of penicillin solution, but later 3 units per cubic centimeter was used. When the penicillin drip is 35 drops a minute, it does not seem possible to administer enough heparin to affect the clotting time.

*Specific Serum Therapy in Typhoid Fever A E Hodgson—p 339

Retinal Detachment—Stallard presents observations on 78 officers and men of the Middle East force who had retinal detachment and were admitted to a military hospital in Egypt for treatment. Seventy-six were operated on for 1 patient surgical treatment was not advised and another made a spon-

taneous recovery The operation was a combination of surface diathermy (90 to 100 milliamperes for eight seconds) placed around the edges of a tear or tears and penetrating diathermy, one, two and very rarely more punctures were made in the sclera with the diathermy needle carrying a current of 40 milliamperes for one second The interretinal fluid was sucked into a glass tube and rubber suction bulb applied to the sclera over the diathermy penetration The 78 patients included 13 with cystic degeneration, 21 with choroidoretinal degeneration 3 with myopia and 41 with trauma The prospect of successful surgical treatment depends much on the type of case The prognosis is reasonably good in early cases when the retinal tear is relatively small and easily accessible, the ocular tissues are in good condition, and an operation by a skilled surgeon is done within a month of the onset of the detachment Large and multiple retinal tears are generally unfavorable, but not always so The prognosis is slightly worse in deep detachments than in shallow ones on account of the distance of the retinal tear from the choroid This is dealt with by passing penetrating diathermy needles through the sclera and choroid sufficiently long to reach the retina but not perforate it Interretinal fluid drains away, and the detachment is shallower for subsequent diathermy applications The prognosis is bad in long-standing cases The incidence of success falls appreciably three months after the onset of detachment but reattachment may occur after four and even ten years Detachment on the nasal side is less serious as regards rapid extension than is detachment originating on the temporal side The prognosis is bad in cases of retinal detachment associated with persistent inflammatory lesions of the choroid, sclera and orbital tissues (orbital cellulitis) Such cases are unfavorable for operation, and if an operation is done through mistaken diagnosis the condition is aggravated Although the number of cases due to trauma peculiar to war is small (18 in this series) these few afford an indication of the seriousness of the prognosis and the difficulties which confront the surgeon in planning an operation on an eye which is often severely damaged as a result of either contusion or a penetrating wound or both

Specific Serum Therapy in Typhoid—Hodgson points out that the work of Felix and his colleagues at the Lister Institute made possible the elaboration of the Vi + O antityphoid serum in which two antibodies are effectively combined the Vi element conferring protection by suppressing the multiplication of virulent strains of *Eberthella typhosa* and the O antibody by neutralizing the endotoxin of that organism This serum has been used in 57 cases of typhoid Seven of the patients died four deaths occurring within eighty hours of arrival at the hospital Twenty of the patients disembarked at the port These seaborne patients had mostly a severe type of typhoid Patients who on admission showed toxic symptoms (general prostration, hyperpyrexia threatened delirium, coma or typhoid state or complications such as hemorrhage or pneumonia), numbering 25 in all received serum Seaborne patients contributed 14 of the 25 serum cases and 4 of the 6 deaths The patients not treated with serum were not controls but rather had mild infections The serum is issued in 33 cc phials, and injection of the contents of one phial intramuscularly (buttock) on three successive days was routine In the very bad cases an initial dose of 66 cc was given This may seem a large amount for one intramuscular injection but if the serum and the syringe have been previously warmed and kept in water at blood heat little discomfort is caused and absorption quickly takes place Under the influence of the serum conditions due to toxemia, excluding hyperpyrexia, abated rapidly improvement appearing often within forty-eight hours and continuing to be sustained, with coincident decrease in signs and increase of strength and well being Six of the severe cases were of the type for which, in other times, but little hope of recovery could have been entertained, they responded promptly Hyperpyrexia was not affected so quickly a fall in temperature taking some days and continuing as a moderately steep lysis Complications such as intestinal hemorrhage or pneumonia, already present when the patient came under treatment, were not influenced by the serum.

Hepatitis After Yellow Fever Inoculation and Infective Hepatitis—Findlay and his associates could find no difference between the two conditions apart from the longer incubation period of postinoculation jaundice This apparent discrepancy disappears when the incubation period of infective hepatitis following subcutaneous injection and the incubation period of postinoculation jaundice following intranasal instillation are considered The authors describe epidemiologic and experimental investigations on infective hepatitis and on postinoculation hepatitis They report possible examples of spread of postinoculation jaundice to contacts who had not been inoculated with icterogenic yellow fever vaccine The incidence of infective hepatitis in childhood and adolescence in a sample of British troops has been ascertained Evidence has been deduced that a previous attack of infective hepatitis gives a certain measure of protection against an attack of postinoculation jaundice though the protection is not absolute A complement fixation test has been developed the results of which tend to show that there is an antigenic relationship between the agents responsible for infective hepatitis and postinoculation jaundice The authors also describe efforts to transmit postinoculation jaundice to man and to various animals Evidence is accumulating that the agents responsible for infective hepatitis and the hepatitis that follows inoculation of icterogenic yellow fever vaccine behave in a similar manner and are antigenically related Until knowledge has further advanced it would be idle to speculate whether these two agents are identical or merely members of a group of icterogenic agents one member of which is responsible for the production of infective hepatitis a second for the hepatitis that is sometimes found in man after the injection of homologous blood or its products and a third, perhaps, for the jaundice in horses that follows the injection of homologous serum

Patulin in the Common Cold—The Medical Research Council reported in November 1943 on the chemical properties and clinical effects of a metabolic product of *Penicillium patulum* Baier called patulin It was shown in a clinical trial on the common cold in naval personnel that when 95 patients treated with patulin were compared with 85 controls the advantage to the treated patients was such that it would usually be regarded as statistically significant Shortly after the publication of the first report an independent group of workers stated that they had been unable to demonstrate any effect of patulin on the common cold The Medical Research Council undertook then an extensive reinvestigation of the claims regarding patulin In a large clinical trial of patulin in widely distributed areas in Great Britain lasting from the beginning of December 1943 to the middle of April 1944 no evidence was found that patulin is effective in the treatment of the common cold

Diencephalohypophysial System and Production of Gonadotropic Hormones—In order to investigate the relationship between the diencephalohypophysial system and sex function, Westman and his associates performed the following experiments on rats (1) They completely separated the hypophysis from its infundibulum and the surrounding pars tuberalis (2) extirpated the processus infundibuli and separated

the processus infundibuli from the infundibulum. In the animals of group 1 the pars distalis showed noticeable microscopic changes. The cells were uniform, and alpha cells were absent. The genital organs exhibited considerable atrophy. In the other two groups of animals in which the connection between the pars tuberalis and the pars distalis was left intact the pars distalis and the genital organs were normal. Determination of the volumes of the pars distalis in the different groups of animals indicated that the genital atrophy was not the result of the reduction in parenchyma. The authors emphasize that the connection between the hypothalamus and the hypophysis consists of two different parts. The one consists of the pars tuberalis with the portal vessels and a specific nerve fiber system, the other is formed by nerve tracts that pass from certain hypothalamic nuclei to the processus infundibuli and to the pars intermedia. The intact connection between the pars tuberalis and the pars distalis is the prerequisite for a normal production of gonadotropic hormones. The impulses which pass from the hypothalamus through the infundibulum and the processus infundibuli are of no significance for the sexual function. The authors think that the contradictory opinions about the significance of the diencephalohypophysial system for the sexual function are partly due to the fact that heretofore the functional differences between the two components of hypophysial attachment have been disregarded.

*Tests for Function of Adrenal Cortex Drs C Galli Mainini E B del Castillo, J Reforzo Membrives and M A Gambin —p 391

Tests for Function of Adrenal Cortex—According to Galli Mainini and his collaborators the diagnosis of diseases caused by hyperfunction of the adrenal cortex is more difficult than the diagnosis of adrenal cortex insufficiency. They describe tests which they carried out on 16 patients with mild forms of adrenogenital syndrome and on the same number of normal persons. Adrenal hyperfunction manifests itself by metabolic disorders of the type which are seen in the Cushing syndrome, namely diminished elimination of chlorides, diminished dextrose tolerance, increased resistance to insulin, increased secretion of nitrogen after ingestion of carbohydrates and fats, and increased elimination of 17 ketosteroids in the urine. The clinical signs of adrenal cortex hyperfunction are sexual and metabolic, either alone or combined. The type of adrenal cortex hyperfunction with clinical symptoms of combined sexual and metabolic disorders is more frequent than that with symptoms of either sexual or metabolic disorders alone.

Procaine Infiltration of Sympathetic Nerve in Frostbites—Buck states that paravertebral sympathectomy, stellectomy and periarterial sympathectomy are contraindicated in early treatment of frostbites because temporary functional impairment should not be combated by producing irreversible anatomic changes. Infiltration of the stellate ganglion with 1 per cent procaine hydrochloride solution in those cases in which the arm is involved and paravertebral infiltration of the sympathetic nerve with the same solution in those cases in which the leg is involved may be performed by any physician in any location and without any special equipment. Infiltration therapy was instituted in cases of fresh frostbite immediately after the cases had reached the author. Infiltration was first performed daily in grave cases and then every second day or at intervals of several days after improvement had been obtained. Bilateral infiltration was performed in cases of bilateral frostbite, and no untoward reactions occurred. Later on infiltration was performed alternately on one side, since a somewhat less accen-

tuated effect was produced likewise at the counter side. From two to fifteen infiltrations were performed until clinical improvement was obtained, pain disappeared and oscillation tracings were restored to normal. Pains will cease immediately for from one to three hours after the first infiltration, they will be less severe and will disappear permanently after repeated infiltrations. Warming and reddening of the skin occur after the infiltration. Single, small, lightly red spots occur on the bluish extremities within five to ten minutes after the infiltration. Their number increases until the entire extremity becomes red except for areas in which the blood supply is definitely injured. Disturbances of sensibility and motor disturbances improved rapidly, sometimes after a single infiltration. A line of demarcation between the dead and the viable tissues became manifest after repeated infiltrations. Amputation should not be performed in the early stage. Moist gangrene did not occur in any of the author's cases. Extensive vascular changes may be prevented in addition to effecting a cure of the local acute frostbite.

Regeneration of Islands of Langerhans—Microscopic studies by von Bakay revealed that the regenerative capacity of the islands of Langerhans is striking during fetal life. The capacity of a newborn infant who died during the delivery of a diabetic mother was manifested by the size of the islands, which had a diameter of 500 to 800 microns. The islands were surrounded by a strong capsule of connective tissue. This tissue formation was peri-insular in all the islands. A few argyrophile fibers were seen along the vessels inside the islands in only a few cases. A true glomus resulted from the dilatation of the capillaries inside the islands and represented another characteristic feature of the condition. The polymorphism of the nuclei was striking and was demonstrated by a large number of giant nuclei. Microscopic examination of 30 specimens from adults showed that postnatal island regeneration occurs under pathologic conditions in cases with impairment of the entire pancreas, i.e. in cases of true diabetes, chronic pancreatitis and pancreatic cirrhosis or in cases in which the functional disturbance results from circulatory insufficiency (arteriosclerosis of the pancreas). The absence of any clinical symptoms of diabetes may be explained by the compensating effect of an intensive regenerative process in the islands of Langerhans. In addition to the hypertrophy of epithelium in the excretory ducts, the increase in the insular system is due to the transformation of the acini and to the segmentation of the old islands. Traces of this regeneration could be found in almost all cases of diabetes. From 3 to 4 new islands were sometimes present adjacent to the proliferating excretory ducts. In 1 case the excretory ducts were considerably dilated as a result of the obstruction from the secretion, the high epithelium was completely flattened. The centers of the islands were pierced by dilated ducts. The origin of these islands from the ducts may be safely assumed. The regenerative tendency is suggested by the fact that in addition to the large hydropic islands others may be found which consist of small, dense, dark colored cells. They were surrounded by a ring of connective tissue which was thicker than that found in normal cases. Vessels are not found within these islands. Their rudimentary character explains the absence of clinical improvement in spite of the regenerative process which was demonstrated on microscopic examination. Regeneration in the head of the pancreas in a patient aged 65 suggested that the regenerative capacity is not reduced with advanced age.

Book Notices

Plaster of Paris Technic By Edwin O. Geckeler, M.D., Associate Professor of Orthopedic Surgery and Chief of the Fracture Service, Hahnemann Medical College and Hospital, Philadelphia. Cloth. Price \$3. Pp. 220 with 208 illustrations. Baltimore: Williams & Wilkins Company, 1944.

For a long time plaster of paris has been indispensable to orthopedic surgery. Calot considered plaster technic so important that he wrote "Show me your plaster" and I will tell you what kind of orthopedist you are." Descriptions of plaster of paris for immobilization are found in ancient history. Various forms of rigid bandages for immobilization were used as early as 1600 B.C. by the Egyptians, who applied gums and waxes to stiffen their surgical dressings in a manner similar to their method of embalming. More than a thousand years later Hippocrates described a similar method of treating broken limbs. The first use of plaster of paris for fractures was reported by Eton, who described a method in which solid gypsum was used by the natives of Basra; this material was poured over limbs in liquid form. In 1852 Matthysen, a medical officer in the Dutch army, described the use of gypsum bandages for treating the wounded in battle.

Although plaster bandages are used almost exclusively in the United States, pattern plaster is preferred by some surgeons abroad. In the latter form the plaster is laid over various parts of the body in shapes already cut out. The "closed plaster" method, popularized by Orr and Trueta, has saved countless lives and limbs in the present world war and permits early evacuation of the wounded with a minimum of hospitalization. The latest development in the use of plaster has been for severe burns. By the early application of plaster of paris to burned limbs, contractures and deformities can be prevented in many cases and minimized in more severe cases. On the modern battlefield plaster of paris can be applied in mobile units without the necessity of hospitalization. Good plaster bandages can be made by almost any one or several brands of ready-made bandages may be purchased.

The combination of text and illustrations is a welcome contribution to the use of plaster of paris. It is an art to use plaster of paris skilfully. This book explains the art. The illustrations are unusually instructive. It is especially gratifying to find that such a monograph is suitable for the instruction of both graduate and undergraduate medical students. This book fills a definite need and undoubtedly will be used extensively. A practical knowledge of this work is not only valuable in everyday practice but is especially important in treatment of war injuries.

The Diabetic A B C: A Practical Book for Patients and Nurses By R. D. Lawrence, M.A., M.D., F.R.C.P., Physician in Charge, Diabetic Department, King's College Hospital, London. Eighth edition. Boards. Price 4s. Pp. 69. London: H. K. Lewis & Co., Ltd., 1944.

The Diabetic A B C War Time Supplement By R. D. Lawrence, M.A., M.D., F.R.C.P., Physician in Charge, Diabetic Department, King's College Hospital, Third edition. Paper. Price 9d. Pp. 16. London: H. K. Lewis & Co., Ltd., 1944.

This edition of Lawrence's "The Diabetic A B C" is contained in two separate booklets, the manual, "A Practical Book for Patients and Nurses," and a wartime supplement. In the supplement the author demonstrates the means by which the diabetic patient can best meet the difficulties that war has imposed on him. Advice is given to the insulin patient who runs risks from air raids and invasion. The author takes cognizance of the special dangers during wartime to the patient whose life depends on insulin and by the withdrawal of which he would be subject to acidosis and coma. He also discusses in detail insulin supplies, food changes, emergency sugar ration, vitamins and the 'Precautions for Diabetics in War-Time' as issued by the Ministry of Health in consultation with the Diabetic Association.

The wartime supplement is timely and of vital interest to all diabetic patients and the author is to be highly complimented for presenting such vital aid in simple form to the patient and nurse.

In the introduction to "The Diabetic A B C" the author states that his book "The Diabetic Life" was written in scientific detail and contained much information unnecessary for the

patient. The present reviewer, who also reviewed "The Diabetic Life" in agreement with the author's opinion. Thus, in the "Diabetic A B C" the author now confines his reader to practical information which will aid him in cooperating with his doctor, to live more easily with minimum discomfort and to maintain better control of his diabetes. The details are adequately and simply discussed under diet line-ration, a method of diet estimation which is popular in England but not in America. Also included are instructions about diet, recipes, insulin doses and their local reactions, insulin overdose and its effects, home life and traveling, as well as other important facts a diabetic patient should know. As was to be expected, this latest work of R. D. Lawrence is a masterful accomplishment of concision and unquestionable authority.

Structure and Function as Seen in the Foot By Frederic Wood Jones, D.Sc., F.R.S., F.R.C.S., Professor of Anatomy, University of Manchester, England. Cloth. Price \$7.50. Pp. 329 with 150 illustrations. Baltimore: William Wood & Company, 1944.

This comprehensive monograph is purely anatomic, including comparative anatomy and biomechanics, and function. The illustrations are profuse and highly instructive. The book will be of keen interest to anatomists and physiologists, and although there is no consideration of diagnosis or treatment it will be of much value to orthopedic surgeons. While many persons take a real delight in their hands, for the most part human beings have but little pride in their feet and it is unfortunate that this is so. The establishment of homologies between the bones, ligaments, muscles and other constituent parts of the hand and foot is an attractive study. It is one of the most delightful bypaths of comparative anatomy and has had a wealth of patient work devoted to it. The subject is of interest to every medical student. As an academic study the establishment of homologies has much to recommend it but for the man who would treat the disabilities of the human foot it is far more important that his knowledge of the part should be of that intimate kind by which each bone, ligament, joint and muscle is known as an individual entity and not by reference to corresponding structures in other parts.

Manual of Psychological Medicine for Practitioners and Students By A. F. Tredgold, M.D., F.R.C.P., F.R.S.E., Consulting Physician to University College Hospital, London. Cloth. Price \$5. Pp. 298. Baltimore: William Wood & Company, 1943.

This timely manual by the author of "Mental Deficiency" presents a description and methods of treatment of the various forms of mental abnormality. With the present wartime need for civilian physicians as well as psychiatrists in the armed forces to attack the problems of psychosomatic medicine and neuropsychiatric disorders it brings together in compact form a great deal of material comprehensive in scope. There are twenty-seven chapters ranging from introduction on the normal mind through classification, etiology, symptomatology, neuroses, psychoses, epilepsy and mental deficiency, and final chapters on legal relationships and sociological considerations. The book is written in a scholarly, yet clear and readable fashion from the biologic approach. It gives basic and essential information of value to the general practitioner as well as the clinical psychologist and psychiatrist. It is also recommended as a condensed textbook for medical students, who will find that it presents a thorough logical and accurate description of the facts of psychiatry known today, thereby providing an excellent grounding in this specialty.

The Electrocardiogram: Its Interpretation and Clinical Application By Louis H. Sigler, M.D., F.A.C.P., Attending Cardiologist and Chief of Cardiac Clinics, Coney Island and Harbor Hospitals, New York. Cloth. Price \$7.50. Pp. 403 with 203 illustrations. New York: Grune & Stratton, 1944.

Fundamentals are discussed in the first four chapters. The remaining twenty-one chapters are clinical. Frequent reference to original material reflects the personal experience of the author. Recent developments are well presented. Bibliographies following each chapter would be more useful if titles were included. Apical lead IVF is used in most illustrations. Sins of commission in legends to figures 28, 29, 31, 32, 76 and 118; of omission in 32 and 102, of speculation in 40 and 143 and of loose terminology in 36, 44, 60, 72, 73, 74 and 116 may confuse. The index is good. The price is high. Student and practitioner will find this book valuable and readable.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

MEASURING PHYSICAL FITNESS

To the Editor—I am interested in determining in as quantitative manner as possible a patient's fatigability. This is an individual who alleges disability because of extreme and undue fatigue. I am unable to find any objective testing methods in the literature more recent than the Schneider test of the first world war. Can you describe any newer testing procedures of value? M D Ohio

ANSWER—Valid and reliable measurement of the ability of a person to resist fatigue is more complex than is usually appreciated. The problems involved have received detailed attention and wide consideration since the beginning of the war. A basic introduction to the limitations and possibilities of such testing may be obtained from Burns, David. *The Assessment of Physical Fitness*, *Nature*, London 144 466 (Sept. 9) 1939, Simonson, Ernst, and Enzer Norbert. *Physiology of Muscular Exercise and Fatigue in Disease*, *Medicine* 21 345 (Dec.) 1942, and Taylor, H. L., and Brozek, J. Symposium on Physiological Aspects of Convalescence and Rehabilitation-Evaluation of Fitness *Federation Proc* 3 216, 1944.

The simplest tests of fitness are cardiovascular and respiratory. Many have been described in the physiologic literature of the last two decades. In addition to the Schneider test, the best and most commonly used include the tests described by Cramp-ton, C. W. *Am J M Sc* 160 721 (Nov.) 1920, Flack, M. *Lancet* 2 593 (Sept. 17) 1921, Turner, A. H. *Am J Physiol* 87 667 (Jan.) 1929, and Master, A. M. *Am Heart J* 10 495 (April) 1935. Numerous motor performance tests may be found in the physical education literature. Representative examples appear in Brace's *Measuring Motor Ability*, New York, A. S. Barnes & Co., 1930. Recent additions should include Cureton's motor fitness screen test (*THE JOURNAL*, Sept. 11, 1943, page 69) and the numerous studies of Brouha and his associates (*New England J Med* 228 473 [April 15] 1943, *Am J Phys Anthropol* 1 95 [March] 1943, *Rev canad de biol* 2 86 [Feb.] 407, 1943, *Yale J Biol & Med* 15 657, 671, 679, 689 [May], 769 781 [July] 1943). The third type of test evaluates the ability to resist fatigue in terms of the response to sensory stimuli. The most recent development in this field is the fusion frequency of flicker measurement described by Simonson and Enzer (*J Indust Hyg & Toxicol* 23 83 [Feb.] 1941).

There is no simple answer to this query. More would have to be known about the case history before specific testing procedures could be recommended as probably capable of reliably differentiating the abnormal person from the normal.

REFRACTORY PRURITUS VULVAE

To the Editor—A married woman aged 52 has had three attacks of pruritus vulvae within the past year. She was hospitalized during each attack for about three weeks. In addition to the intense itching there was severe pain which required an opiate to relieve. There was also a considerable degree of dermatitis extending upward and outward to the thighs. Therapy involved local applications of various ointments, hot packs, hot baths, douches, heavy doses of vitamins and x rays, apparently nothing has given much relief. Can you suggest treatment for this condition? M D Virginia

ANSWER—It is assumed that a general physical examination has been made in this case and especially that the urine has been examined for the presence of sugar. The most common conditions which cause intractable itching in a woman 52 years of age are *Trichomonas vaginalis* vaginitis, moniliasis infection, kraurosis vulvae or leukoplakia, senile vaginitis, eczema and, of course, some general disorder such as diabetes, leukemia or Hodgkin's disease.

Naturally the treatment depends on the cause if one can be found. Hanging drop examinations of the fresh discharge from the vagina or stained slides will reveal the presence of *Trichomonas* or *Monilia* if either one is present. Treatment of these afflictions nearly always brings relief from the itching, but recurrences are common. In kraurosis vulvae or leukoplakia the appearance will depend on the stage of the disease. In the first stage the vulva is swollen, red, bruised and painful. Later the tissues atrophy but the skin itself is thickened, indurated and leathery. Still later the skin becomes smooth and glistening and resembles parchment. The treatment of choice is vulvectomy both because other treatment is temporary and because in

about half the women cancer will develop after a number of years. Temporary treatment with estrogens is most helpful and is the same as for senile vaginitis. In the latter condition the vagina is shorter and narrower than normal, and the introitus is considerably constricted. The mucosa is thinned out and easily traumatized. The best treatment is the use of estrogens to restore the senile vaginal mucosa to that of a normal premenopausal condition but unfortunately the change is not permanent. In four to six weeks after the cessation of treatment the vaginal mucosa rapidly returns to its previous atrophic condition. It is best to treat women having senile vaginitis with an injection of 10,000 rat units (50,000 international units) of estrogenic substance once or twice a week for six or eight weeks. In addition, the patient should insert into the vagina every night a suppository containing 400 rat units (2,000 international units) of estrogenic substance. When itching is intense and the hypodermic and vaginal treatment do not relieve the pruritus quickly enough, a saline containing estrogenic substance should be prescribed. Usually relief is obtained within two weeks after treatment is started. If symptoms reappear, more injections of estrogen should be given. A number of courses may have to be administered. Uterine bleeding may result from this treatment, so the patient should be warned of this possibility.

If a medical disorder is found, specific therapy must be directed against it, of course.

In some cases which do not yield to local or endocrine therapy, the subcutaneous injection of alcohol may be tried according to the method of Jacoby (*Am J Obst & Gynec* 29 604 [April] 1935). If this does not help, one may resort to resection of the sensory nerves of the vulva (Learmonth, Montgomery and Counsellor *Arch Surg* 26 50 [Jan.] 1933) or a vulvectomy may be done.

HEMOSTASIS AFTER TONSILLECTOMY

To the Editor—Among the staff members at the local hospital there seems to be some difference of opinion as to the proper method of hemostasis after tonsillectomy. Most of them pay little attention to bleeding from the tonsil fossa unless it is profuse. Venous oozing of a small amount is more or less ignored. The intent seems to be to finish as soon as possible without much concern for a dry field. Other doctors contend that hemostasis should be as complete as for any other operation and that the field should be completely dry before finishing. The first group contends that venous oozing from a raw surface as the tonsil fossa is natural and that it will stop spontaneously after the operation which is true in most cases. Isn't post-tonsillectomy hemorrhage within eight hours much less likely to occur if hemostasis has been complete? What percentage of these hemorrhages is the direct result of failure to secure a dry field at the time of operation? Is there tonsillectomy hemorrhage within the first eight to twelve hours in (a) children and (b) adults? In this connection there is also a difference of opinion as to the proper use of a La Force tonsillectome with hemostatic and cutting blades. One group of doctors leaves the hemostatic blade clamped down only long enough to remove and inspect the tonsil. The other group leaves the hemostatic blade clamped for three to five minutes, contending that hemostasis is better. Which technic is the better? What are the most satisfactory hemostatic agents for topical application to the tonsil fossa to control bleeding? An early reply will be appreciated. M D Utah

ANSWER—There should be no great difference of opinion as to the necessity for stopping important bleeding in the tonsillar fossae after tonsillectomy. The only room for debate will be in those cases in which the bleeding is obviously slight. Here it is true that many will rely on experience, which indicates that most of the time this will stop spontaneously. There are others, however, who insist on a dry fossa being present before a patient is allowed to leave the operating room. This care is to be commended, and there is good reason to believe that those who follow this practice will have much less bleeding which requires attention. That this is so may not be apparent over a short period of observation nor will it seem to be so in the practice of an occasional operator. Such care is rewarded in the diminished number of patients who will lose noteworthy amounts of blood, in the smaller number of persons requiring a second anesthetic to carry out this procedure and in undesirable psychologic reactions, particularly in children, who do not take kindly to the necessary handling.

It is not possible to give accurate statistics as to the frequency of primary tonsillar bleeding (i.e., that occurring any time in the first twenty-four hours after operation). It will vary with different methods with different operators and perhaps with different seasons and parts of the country. It has been reduced in the practice of some to much less than 1 per cent. So too the percentage of hemorrhages occurring as a result of failure to secure a dry field cannot be determined for who attempts to gather such figures or who will admit negligence? The important thing is that the surgeon doing tonsillectomies is bound no less than the general body of surgeons to observe the rules that apply throughout this field to the control of bleeding. Hemostasis is an important part of the discipline of surgery, and laxity should never be permitted.

Primary hemorrhage (i. e. that occurring within the first twenty-four hours) occurs both in children and in adults.

The crushing blade of the La Forge tonsillectomy should be left on for a few minutes before the cutting blade is used, for that is the rationale of its use, namely that crushing tissues promotes hemostasis.

There are many agents for topical applications to the tonsil fossae after operation. A satisfactory one is made of tannic acid crystals to which enough epinephrine hydrochloride solution (1:1000) is added to give a consistency of mustard. Some use gallic acid crystals and others a mixture of equal parts of the two. The iron salts also have been and are popular in various solutions. They leave an undesirable eschar, however, and the tannic acid preparations described are perhaps more desirable. This is especially true if one considers that topical applications cannot be depended on to stop bleeding of note. They are useful for stopping trivial oozing. All other types of bleeding should be handled in the accepted surgical fashion, namely by pressure, clamping or the judicious use of the ligature.

PYREXIA OF UNDETERMINED ORIGIN

To the Editor—A boy aged 9 has had a low grade fever for the past three years (98.6 to 100.8 F by mouth). The present illness began with a sudden severe tonsillitis and bronchitis; the fever which was high lasted for three weeks. He has continued to have the low grade fever since then. He had lobar pneumonia at the age of 1½ years and measles following intestinal flu at 2½. Raw milk has been used at different intervals since the age of 2. Physical examination is normal except for height 54½ inches (138 cm) and weight 83½ pounds (38 Kg). Examination of the heart reveals a soft systolic mitral murmur not transmitted which has not increased during the past two years. Laboratory examination showed red blood cells 5,200,000, hemoglobin 15 Gm, white blood cell 8,600, polymorphonuclears 55, lymphocytes 41, monocytes 2, eosinophils 1 and transitional cells 1. The sedimentation test repeated several times gave a rate of 10 mm in one hour. The urine is normal. The results of the tuberculin test from 1:1000 up to 1 mg were all normal. Agglutination tests for typhoid, *Brucella abortus* and *Brucella melitensis* were normal; there were no heterophile antibodies. Examination of the blood chemistry revealed cholesterol 235, chloride 615, calcium 10.8, phosphorus 4.0, total protein 6.72, sugar 90 and Weltman 9. Negative cultures were obtained from the blood, urine, nose, throat, showed pneumococcus, *Micrococcus flavus* and gamma streptococcus. A skin test performed with *Brucella melitensis* with 1:1000 dilution was negative with negative control. A chest plate gave a normal result; the heart is normal in size and outline. X-ray examination of the accessory nasal sinuses revealed no abnormality. Is a diagnosis of brucellosis justified? If so, what treatment is recommended? Has rheumatic fever been ruled out? Should tonsillectomy be performed because this child has two or three severe attacks of tonsillitis a year? Have you any further suggestions for work-up of this case?

William F. Mahoney, M.D., Saco, Maine

ANSWER—If the patient is well active and gaining weight and height normally, there may be no need for particular concern. The boy's temperature, which is higher than the average, may be normal for him and not fever at all (Reimann, H. A. The Problem of Long Continued Low Grade Fever. *THE JOURNAL*, Oct 3 1936, p. 1089). He is taller and heavier for his age than the average, but the cardiac murmur is probably not of significance. However, as in all cases of this type, continued unobtrusive observation is wise.

The history of repeated respiratory tract infections beginning in infancy brings up the possibility of bronchiectasis in spite of the normal roentgenogram. If cough with sputum develops, it may be desirable to make a bronchogram after injecting iodized oil. If he has chronic brucellosis, one would not expect such an evenness of fever for three years, but rather remissions, slight relapses and other signs and symptoms. Furthermore, brucellosis cannot be diagnosed solely from a positive skin test. Without other evidence, rheumatic fever is also an unlikely diagnosis.

A history of repeated attacks of severe tonsillitis is the prime and almost only indication for tonsillectomy generally, if actual tonsillitis continues to recur in this patient the tonsils should be removed.

NEW CURES FOR LEUKEMIA

To the Editor—Is there any new drug that is of benefit in the treatment of an acute lymphatic leukemia? While in Chicago I noticed in one of the daily papers that some new drug was being used on a patient in Ohio but the press did not mention the name of the preparation.

Bernard J. Baute, M.D., Lebanon, Ky.

ANSWER—There is no new drug which offers any hope in the treatment of acute leukemia. Reports of cures or new treatments for leukemia appear frequently in the press. The index of one large newspaper contains seven reports of new treatments for leukemia in the past six years; none of these have proved successful. If a specific agent for leukemia is discovered, it would undoubtedly receive prompt recognition in *THE JOURNAL*.

PAINFUL AXILLARY MASSES IN PREGNANCY

To the Editor—A woman aged 23 is now fourteen weeks pregnant. When she was about eight weeks pregnant she began complaining of pain and swelling in the right axilla. A few weeks later the axilla became swollen and painful. The mass in the right axilla is about the size of a large lemon while that in the left is about the size of a hen's egg. Both masses are tender to pressure and because of the pain the patient is forced to sleep on her back. I can find no suggestion of a nipple or other opening in the region of these masses. I have had 2 patients in the past with swollen axillary masses but they were not apparent until a few days prior to delivery and promptly subsided shortly after delivery. I think I think to not allowing the mothers to nurse the babies. What treatment would you suggest? Is it good practice to remove this tissue surgically?

M.D. West Virginia

ANSWER—The masses described are almost certainly accessory mammary tissue which are stimulated to grow by the hormones produced in pregnancy. Generally these masses give no trouble until after delivery but not infrequently they are distressing during pregnancy. There is no need for surgery. In some cases the administration of diethylstilbestrol reduces the size of the swellings and the pain they cause. The patient may be given 5 mg of any one of the Council accepted commercial preparations morning and night for five days. It may be necessary to repeat such a course of therapy one or more times during pregnancy and in the puerperium. The results are comparable to the relief of congestion and pain in the breasts during the first few days post partum obtained by the use of diethylstilbestrol.

MERCURIAL DIURETICS FOR PATIENT WITH CONGESTIVE HEART FAILURE

To the Editor—A man aged 56 has hypertensive cardiovascular disease. His cardiac reserve has been diminishing in the past two years. He now develops massive edema of the legs and some fluid collects in the abdomen and chest. This can be made to disappear with a few intramuscular injections of salyrgan and theophylline but soon recurs. Is it safe to continue using the salyrgan and theophylline two or three times a week to keep his edema down? His urine has 3 plus albumin but no cells nor casts. His edema cannot be controlled by bed rest and digitalis. He is uncomfortable when the fluid collects and has to sit in a chair at night. When the fluid is gone he is fairly comfortable.

M.D. New Jersey

ANSWER—It is considered safe to inject a mercurial diuretic more than once a week and for an indefinite period as long as the patient responds with a satisfactory diuresis. It is assumed that the patient is on a salt poor diet and restricted as to fluid intake. The presence of albuminuria is not a contraindication to the use of mercurial diuretics for a patient with congestive heart failure; neither is the presence of a moderately elevated nonprotein or urea nitrogen in the blood provided the creatinine is normal. If ammonium chloride is used in adequate dosage (6 Gm daily in enteric coated capsules) the number of mercurial injections may be reduced to less than two a week.

PHYSICAL INFLUENCES ON LOCALIZATION OF SKIN LESIONS

To the Editor—A boy aged 6 years was injured in a fall and received a simple fracture of the left radius without displacement. A supporting plaster splint was applied from just below the elbow to the palm and held in place with a muslin bandage. No stockinet or other material was used between the skin and the plaster. The splint was worn continuously for about three weeks after which it was worn during the day for protection only. About four weeks after the injury the child developed chickenpox and the splint was removed. The rash was fairly heavy and evenly scattered except for that part of the left forearm which had been in contact with the plaster. Over this area the lesions were exceptionally numerous. The illness took the usual course and there were no complications. A dark suntan was present over the upper half of the body except the part of the left arm covered with the bandage. The lesions on the extensor surface of the forearm where only the muslin bandage had covered the skin were no more numerous than elsewhere. What is the basis for the predilection of the pox for the skin area which has been in contact with the plaster splint even though the splint was not worn after the rash began to appear?

Ira D. Hirschy, Major, M.C.A.U.S.

ANSWER—Every dermatologist is familiar with instances of peculiar localization and distribution of lesions determined by physical means. Sometimes the influence of these agents is felt long afterward. This has given rise to the expression that the skin has a long memory. An area of sunburn zones of pressure from suspenders, the site of a chemical irritation or points of trauma may be the ones where a future eruption does or does not occur. It has come to be accepted though not fully understood that the skin may be sensitized by substances such as poison ivy resin. The apparently normal skin between attacks harbors invisible changes that give it certain potentialities. In some manner also physical agents unquestionably leave a durable impress on tissues. What these changes are and how they occur is much less understood than even the phenomena of allergy.

The study of air-borne infection is of relatively recent origin. Several circumstances in particular have accelerated investigation in this field during the past two to three years, namely the development of more efficient and quantitative methods for recovering bacteria from the air, progress in methods of aerial disinfection and the war. The fact that between one third and one half of all illness in army camps is caused by diseases of the respiratory tract coupled with the lack of any effective measures for reducing the incidence of such diseases indicated the urgency of intensive study of this problem in the Army. Before the war began, a number of special commissions were set up under the Board for the Investigation and Control of Influenza and Other Epidemic Diseases, Preventive Medicine Service, Office of the Surgeon General, U S Army. Certain of these commissions were assigned to study different specific diseases of the respiratory tract and one to the general problem of air-borne infection. The Commission on Air-Borne Infections¹ has had the opportunity during the past two and a half years to carry on a study of this subject both in the laboratory at the University of Chicago and in the field at Chanute Field, Camp Carson and Peterson Field.² While the ultimate aim of these investigations was the development of measures

to reduce the incidence of acute diseases of the respiratory tract in army camps, it was evident that much more knowledge concerning the nature of air-borne disease would have to be obtained before effective means of control could be devised. Such essential information comprised a better understanding of (1) the sources from which infectious agents are dispersed into the air, (2) the relationship of aerial contamination to the spread of disease and (3) the various factors which influence the survival of pathogenic agents in the environment.

In designating an infectious disease as air borne, it should be kept in mind that this descriptive term indicates that the disease may be transmitted through the air or perhaps is acquired principally by this route but does not exclude other modes of transmission. Thus, secretions carrying the etiologic agents of acute respiratory disease may be passed to the new host directly by contact of lips or hands or less directly through contaminated food, eating utensils and other objects. Infection through the air may occur either from exposure, at close proximity to diseased persons who eject large numbers of infectious droplets in sneezing, coughing and talking³ or as a result of inhaling particulate infectious material floating in the atmosphere of an enclosed space either at a distance from or subsequent to the departure of the diseased person. The area of high atmospheric infectivity resulting from coughing or sneezing is probably a relatively small one. Jennison's⁴ stroboscopic photographs of a sneeze show that the droplets are projected not more than 2 to 3 feet and Hare's⁵ experiments with cough plates placed in an arc in front of the subject indicate an even shorter distance of dispersion produced by a cough. The larger droplets, constituting the bulk of the infectious secretion, settle out quickly to the floor or other surfaces, and the smaller ones of 2 to 3 microns or less evaporate rapidly and are carried away on air currents. Certain of the earlier workers in this field considered that such small dried "droplet nuclei" (Wells⁶) constituted the principal source of infectious particles in the air. More recently English and Canadian investigators⁷ have shown that bedclothes and floor dust in the vicinity of patients suffering from certain diseases of the respira-

3 Jennison's⁴ stroboscopic photographs show that the relative number of droplets produced by these activities is in the order named. Sneezing is by far the most productive of aerial contamination. Most of the droplets however leave by way of the mouth.

2 Much of the unpublished work of the commission is referred to in various parts of the paper. These observations will be reported later in full by the various members of the group.

tory tract constitute reservoirs from which infectious agents are redispersed into the air on agitation. We were able to confirm readily the finding that disturbance of the environment, bedclothes and floor dust of patients suffering from one type of respiratory infection, namely hemolytic streptococcus, caused an increase in the number of these micro-organisms in the air but were then faced with the problem of the relative importance of these sources of pathogenic bacteria as contributing to aerial contamination.

In order to recover bacteria from the air and other parts of the environment in a quantitative manner it was necessary to devise special apparatus for this purpose. Two kinds of bacterial air samplers have been developed. One utilizes the principle of atomization to trap the bacterial particles in broth.⁸ It is simple in operation and highly efficient and will recover 90 to 95 per cent or more of bacteria from air sampled at the rate of 1 cubic foot per minute. Aliquots of the

Fig 1—Apparatus for collection of bacteria from the air

broth are plated in blood agar. The other, pictured in figure 1, is of simpler design and operates by bubbling air at an equally rapid rate into a large test tube containing broth, with two or three drops of sterile olive oil added to prevent foaming. The rapid dispersion of the air through the fluid against the test tube walls results in the retention in the broth of approximately 90 per cent of air-suspended bacteria. While the efficiency of this apparatus is slightly less than that of the atomizer sampler, the fact that it requires no special glass blowing skill for construction and can be made up in any numbers from readily purchasable glassware renders it more generally usable.⁹ With both types of sampler the air flow is measured by a simple flowmeter designed for this purpose¹⁰ (fig 1). For culturing bedclothes or the floor a funnel is attached by means of a rubber tube to the inlet of the "bubbler sampler" and it is used in the same manner as a vacuum cleaner. Blood agar plates exposed for varying periods of time were employed as a concomitant means for detecting the presence of air-borne bacteria. The usefulness and limitations of this method are described elsewhere.¹¹

Since hemolytic streptococcus infection of the upper respiratory tract constitutes a prevalent and important disease and since this micro-organism is much easier

to isolate and trace than any other respiratory disease agent, our investigations in army hospitals and barracks have been centered principally on the hemolytic streptococcus. We have amplified the field observations by studies in the laboratory on this and other respiratory pathogens, e. g. pneumococcus, staphylococcus and influenza virus.

SOURCES FROM WHICH STREPTOCOCCI ARE DISPERSED INTO THE AIR

As others have previously found and as we have been able to demonstrate clearly in barracks¹² and wards,¹³ the bacterial population in the air is in general proportional to the number of persons in the occupied space and the degree of their activity. The total number of bacteria in the air of an occupied barrack is at its lowest when the men are sleeping and may rise from less than 100 per cubic foot at this time to many thousands during the peak of morning activity getting up, dressing, bedmaking and sweeping (fig 3). Similarly, in environments (wards) occupied by patients with active streptococcal nasopharyngitis or scarlet fever, air samples taken while the ward was quiet yielded fewer than 2 hemolytic streptococci per cubic foot of air, whereas during dry sweeping or bedmaking the counts increased frequently to 15 or 20. Cultures of the bedclothes and floor dust in such wards revealed pronounced contamination of several or many of the beds and the floor round about. From 10,000 to 100,000 or more hemolytic streptococci could be recovered from a single sheet or blanket on the beds of certain patients and a million or more from the dust under the bed. Furthermore, it was found that streptococci could be recovered from pajamas and other clothing as well as from the skin of the patient.

Our observations left no doubt that disturbance of bedding clothing and floor contributed greatly to the numbers of hemolytic streptococci in the air but that such increases were temporary, lasting not much beyond the period of disturbance, and hence the question as to whether the bulk of air-borne streptococci present during the quiet periods came directly from the patients as fine droplets or on dust and lint from the secondary reservoirs remained unanswered. A conclusive answer to this question may not be very important, since we have evidence both experimental and clinical¹³ that dosage is very important in determining whether or not air-borne infection occurs, and it may well be that infection is much more likely to occur in the relatively brief periods of high concentration of streptococci or other disease agents in the air than at other times. Furthermore, a certain degree of disturbance of the secondary reservoirs is constantly occurring as long as there are occupants in the space. Observations in barracks contaminated with hemolytic streptococci tend to bear this out.

RELATIONSHIP OF AERIAL CONTAMINATION TO SPREAD OF DISEASE

Cultures of the air in wards where secondary or cross infections with hemolytic streptococci were occurring have revealed the presence of those streptococcus types causing the infections. Furthermore, when such infections were caused by several different types the

predominant air-borne streptococcus was found to be of the same type as that causing the largest number of infections. Occasionally a series of cross infections were due to a single type and only this type of streptococcus was isolated from the air. In 1 such instance a type 17 hemolytic streptococcus was isolated from the air of a ward housing "common respiratory disease" patients two days before the first infection, scarlet fever due to type 17, occurred. In the ensuing five days, during which time air cultures showed a great increase in the numbers of type 17 hemolytic streptococci, 7 additional patients became infected with this particular micro-organism, some with scarlet fever, others with tonsillitis.¹¹

Studies in barracks have shown the same association between air-borne streptococci and the occurrence of infection due to a given type of hemolytic streptococcus. In several instances in which one whole story of a barrack has shown definite contamination of the bedclothes and floor dust with a predominant type of streptococcus (the same as that of the initially infected person) cultures of the air have revealed only this type or relatively few streptococci of another type. In two such barracks, all of the ten or more infections occurring during a brief interval of time were due to this one predominant type.

The relationship of hemolytic streptococcus carriers to aerial contamination and spread of infection until recently has been largely conjectural. Earlier studies showed that the presence of even a high percentage of persons (as many as 50 per cent of the patients in a 32 bed ward) harboring group A streptococci in their throats might not result in secondary infections or new carriers,¹⁴ or more than a minimal contamination of the air with these micro-organisms. On the other hand the introduction into a respiratory disease ward of a single individual carrier (infected, convalescent or well person) of any one of a number of group A hemolytic streptococcus types was sometimes followed by a widespread dispersal of these micro-organisms in the environment and multiple cross infections with the specific type. Quantitative bacteriologic studies of the bedclothes, hands and air in the immediate environment of such individuals have shown that they are capable of rapid and definite contamination of their surroundings. Further investigation showed that the saliva of many of these "dispersers" contained large numbers of hemolytic streptococci but revealed no quantitative relationship between streptococcus saliva content and dispersing capacity. It was not until culturing of the nose as well as the throat was instituted that a means of detection of the "dangerous carrier" was found. An extensive series of observations has shown (1) that patients whose nose cultures were strongly positive expelled hundreds to thousands as many hemolytic streptococci as those individuals whose nose cultures were negative and (2) that all patients or carriers responsible for the infection of other persons were found to exhibit positive nose cultures, although not every individual whose nose culture was positive expelled very large numbers of hemolytic streptococci.

While the foregoing observations provide no conclusive proof that streptococcal infection of the respiratory tract does occur through the medium of the air, a considerable body of indirect evidence strongly supports this assumption. Furthermore, experimental air-

borne transmission to animals of certain human diseases e.g. streptococcal, pneumococcal and influenzal infections, leaves little doubt that human beings may contract these infections in the same manner. This subject has been reviewed in an earlier publication.¹⁵

FACTORS INFLUENCING THE SURVIVAL OF PATHOGENIC AGENTS IN THE ENVIRONMENT

Knowledge of the length of time disease agents of the respiratory tract can survive outside the body under varying conditions is essential to an understanding of the various aspects of air-borne infection. While this field has not been adequately explored certain facts have been brought out. Others¹⁶ have observed that light and heat shorten the life span of certain pathogenic bacteria. In addition we have found that atmospheric humidity plays a very important role in determining the duration of viability of several different disease agents. Hemolytic streptococci suspended in saliva and dispersed as a fine mist into a dry atmosphere can be recovered from the air twenty-four hours later.¹⁷ Blankets contaminated with hemolytic streptococci have been isolated in a dry atmosphere and when sampled at the end of four months still exhibited considerable numbers of these micro-organisms. Although adequate comparative studies in atmospheres of high relative humidity have not been carried out in the case of the streptococcus, preliminary tests indicate that in a moist atmosphere their viability is much briefer. However the effect of varying humidity on air-borne influenza virus has been studied extensively. It was found that in relative humidities of 80 to 90 per cent the virus survived less than one hour but could be detected in dry air of 25 to 30 per cent humidity at the end of thirty-six hours.¹⁸ Furthermore, living influenza virus could be recovered from the air following shaking of a canvas floor covering as long as six days after it had been sprayed into a room with a dry atmosphere.¹⁹ The latter finding indicates that under suitable conditions influenza and not improbably other respiratory disease viruses may accumulate in the patient's environment and be redistributed into the air in the same manner as bacteria.

CONTROL OF SECONDARY RESERVOIRS OF INFECTION

It became evident from these studies that a successful attack on the problem of the prevention of air-borne infection must include control of the secondary reservoirs of disease agents in addition to measures for disinfecting the air, such as glycol vapors or ultraviolet radiation.

(a) *Floor Treatment to Hold Dust and Lint*—A number of compounds for floor treatment were tested by means of scattering dust and fine lint on the treated areas and observing through a microscope the holding power of the surface when a strong breeze from an electric fan was directed on it. On wood floors a single coat of pale paraffin oil was found to be highly effective.

in holding both lint and dust. Tests repeated over a period of many weeks showed this property to be undiminished. Van den Ende⁷ and Thomas⁷ used spindle oil for this purpose. For highly polished floors and linoleum, which were made somewhat slippery by oil, a compound consisting of urea 5 per cent, ninol²⁰ 3 per cent and roccal²¹ 0.1 per cent was found to be satisfactory. This mixture dried quickly but held enough moisture in the urea crystals and ninol to produce wetting of particular matter falling on its surface. Furthermore, the treated surface exerted a bactericidal action. The disadvantage of the urea-ninol-roccal compound is that it must be reapplied frequently and can be employed only on nonporous surfaces.

(b) *Method for Oil Treatment of Bedclothes*—It seemed obvious that the ideal treatment of bedding would be one that rendered it bactericidal as well as dustless and lintless. However, after a long series of experiments with a considerable number of different preparations both bactericidal and nonbactericidal it became evident that any agent which would simply hold particulate matter in the blanket or other material was just as effective in preventing dispersal of bacteria into the air as one which might exert a germicidal action. It was found that medicinal liquid petrolatum was an excellent agent for this purpose. Oil treatment of blankets was first investigated by certain English workers,²² but the formulas which they employed contained ingredients that made them unsatisfactory for practical use.

The principal problems were, first, to develop a satisfactory method for applying oil to blankets, sheets and the like and, second, to devise a simple and rapid means for testing the effectiveness of an oil application in retaining lint and bacteria. Oil treatment of bedding was found to be most adequately achieved by means of water-oil emulsions which were employed as a final rinse in the laundering process. These emulsions had

Fig. 2—Reduction in bacterial content of ward air by floor treatment and use of oiled bedclothes. Consecutive air samples twenty minutes each. Solid line control periods; broken line period of treatment.

to meet certain requirements, namely very fine dispersion, stability, lack of any irritation to the skin and absence of odor. A base for an oil emulsion which most nearly met these requirements consisted of mineral oil (Fractol A) 88.0 Gm, oleic acid (purified) 8.9 Gm

²⁰ A synthetic detergent manufactured by the Ninol Laboratories Chicago.

²¹ The commercial form of Zephiran supplied by the Alba Pharmaceutical Company, New York.

²² Van den Ende, Lush and Edward. Thomas and Van den Ende⁷

triethanolamine 3.9 Gm and lecithin 0.01 Gm.²³ When poured into water and mixed well, a milky emulsion results which consists of particles so fine that they exhibit brownian movement. Patch tests on 175 persons with a 25 per cent emulsion of the oil base were all negative.²⁴ The percentage of oil in the treated material was determined by extracting the oil from the test sample with chloroform and then evaporating the solvent and weighing the residue.

In order to test the effectiveness of the different oil preparations (principally the varying percentages of oil in the fabric) a method was devised in which counts were made of the number of particles released from the treated fabric following a uniform degree of agitation. Blankets treated with 1 or 2 per cent oil emulsions and tested in this manner exhibited a reduction of 95 to 98 per cent in the lint and bacteria released as compared with control pieces of the same blanket. Such treated blankets and other bedclothes were indistinguishable to smell or touch from untreated ones.

It was essential to determine whether oiling of bedclothes, especially blankets, contributed any increased fire hazard. An extensive series of combustion and ignition tests on oil-treated blankets, comforters and sheets undertaken by the National Bureau of Standards showed that percentages of oil considerably above the maximum which we proposed to employ (namely, 3 to 4 per cent) involved no fire risk.²⁵

TESTS OF THE EFFECTIVENESS OF OILING FLOORS AND BEDDING

(a) *On Bacterial Content of Air*—Tests of these relatively simple means for dust control were carried out in army hospital wards and barracks. In wards it was found that the rise in bacterial content of the air resulting from dry sweeping the untreated floor was almost entirely prevented by previous mopping or by preparation of the floor with the urea-ninol-roccal compound. The dust-retaining effect of the floor compound lasted much longer than did that of mopping alone and resulted in lower bacterial counts during periods of relative quietness in the ward. It was necessary, however, to reapply the floor compound daily. The use of oiled bedclothes brought about an almost equally striking reduction in the aerial dispersion of bacteria which ordinarily occurs during bedmaking. These effects are shown in figure 2. Equivalent reduction in the numbers of air-borne hemolytic streptococci was obtained. The bacterial counts and the percentage of reductions brought about by oiling the bedclothes are given in the accompanying table.

In barracks, which represent a much dustier environment than hospital wards, the results of oiling were even more striking. To determine the maximum effects of these dust control measures it was necessary to secure cultures of the air before, during and after the daily period of greatest activity in the barracks. The first air samples were taken when the occupants were all asleep and continued through a period of two hours while the men were getting up, dressing, making beds and being otherwise occupied. The rise and fall in

²³ This is a modification of an emulsion described by the Carbide and Carbon Chemicals Corporation.

²⁴ While this emulsion has been the one principally used in our study and many thousands of bedclothes have been treated by this means with satisfactory results we have found that certain difficulties may be encountered in its routine use in laundry procedures. For this reason we are testing other emulsions which give promise of eliminating these difficulties. Details of this subject together with an account of the laundry procedures involved in oiling bedclothes, will be published.

²⁵ Dr. Lyman J. Briggs, director of the National Bureau of Standards and Mr. S. H. Ingberg, chief of the Fire Resistance Section, made these studies.

the numbers of bacteria in the air of a barracks during this time is shown by the graph in figure 3, which represents the average of more than 300 air cultures taken in treated and untreated barracks housing men of the same company. It will be observed that oiling the floors reduced by approximately 70 per cent the peak in the number of air-borne bacteria which occurred in the control barracks during the same period of maximum

Effect of Oiled Bedclothes on the Bacterial Content of Ward Air During Bedmaking

	Total Bacteria per Cubic Foot		Hemolytic Streptococci per 10 Cubic Feet	
	Quiet Period	During Bedmaking	Quiet Period	During Bedmaking
Untreated bedclothes	118	938	6	24
Treated bedclothes	75	276	0	4
Per cent reduction by treated bedclothes	36.4	70.6	100	83.3

Each figure is an average of about ten days tests on a twelve bed ward containing 9 to 12 patients

activity. Oiled bedding plus oiled floors effected a further reduction to about 90 per cent of the bacterial counts in the control barracks. In fact activity of the occupants of the completely oiled barracks caused very little change in the number of air-suspended bacteria. The small early morning rise shown in the graph might well be associated with the liberation of bacteria from the men's clothing during dressing. Though hemolytic streptococci were seldom found in the air of the oiled barracks, very large numbers were not infrequently recovered from the air of untreated ones.

(b) *On Bacteria Recoverable from Blankets*—An extensive series of cultures from oiled blankets in barracks with oiled floors yielded only about one-seventh the number of bacteria recovered from untreated but washed blankets in control barracks. Very few hemolytic streptococci were obtained from the oiled blankets, while in numerous instances great numbers were recovered from unoiled blankets. Tests repeated during a period of two months after placing the oiled blankets on the beds showed no apparent diminution in their bacteria-holding property.

(c) *On the Incidence of Acute Respiratory Infection*—In view of these results and the difficulty of utilizing glycol vapors or ultraviolet radiation in a large number of barracks, a study of the effect of oiling floors and bedclothes on the incidence of acute respiratory disease in a considerable body of troops was instituted. The major part of the test consisted in the oiling of every other barracks. In certain areas the company constituted the test and control unit. The number of hospital admissions for acute infections of the respiratory tract was chosen as the index of comparison. At the date of writing the test has not extended over a sufficient period of time to permit final conclusions, nor have the considerable body of data already at hand been adequately analyzed, but it may be said that the results so far obtained point to a significant reduction in the number of hospital admissions for acute respiratory disease from the oiled barracks.

USE OF TRIETHYLENE GLYCOL VAPOR

We have practically no information concerning the minimum concentration of any air-borne disease agent necessary to produce infection of the exposed individual and only very meager data on the numbers of hemolytic streptococci in the air of environments where infections

with this micro-organism are taking place. Certain evidence derived from experimental air-borne infection in animals indicates that dosage is a determining factor and depends on the concentration of the infectious agent in the inhaled air and the length of the exposure or both. It has been found that if the concentration in the air of a given disease agent, e. g. influenza virus, falls below a certain level, animals breathing the air even for a long period of time fail to contract infection, in spite of the inhalation of detectable amounts which can be demonstrated by suitable methods. Thus it seems not unlikely that in certain situations appropriate measures for controlling dispersal of infectious agents from secondary reservoirs might hold their concentration in the air at a sufficiently low level that even highly susceptible persons would escape infection. However, we know from experience that, even though the incidence of respiratory disease in such controlled environments can be reduced, infections may still continue to occur. Whether these are due to a minimum dispersion of disease agents from contaminated surfaces or to droplets ejected directly from the infectious individuals or to exposure outside the living quarters is not known. At any rate it seems evident that more complete control of the transmission of acute infection of the respiratory tract requires some form of arial disinfection.

Ultraviolet radiation has been employed for this purpose for some time and is now receiving further extensive tests under controlled conditions by one of the other branches of the armed forces. The use of certain glycol vapors offers another method for killing air-borne disease agents. It has been found that some of the glycols, especially propylene glycol and triethylene glycol, when dispersed into an enclosed atmosphere in vapor form, exert a very strong lethal action on pathogenic bacteria of the respiratory tract as well as on influenza virus.²⁶ The amounts required to produce a germicidal atmosphere are so small that relatively large

Fig 3—Control of bacterial content of air in barracks by oiling floors and barracks blankets

spaces could be treated at low cost. A concentration of 1 cc of triethylene glycol vaporized into 10,000 cubic feet of air produces almost immediate death of pneumococci, streptococci and influenza virus previously dis-

²⁶ Robertson, O. H., Bigg, E., Puck, T. T. and Miller, B. F. The Bactericidal Action of Propylene Glycol Vapor on Micro-Organisms Suspended in Air. I. J. Exper. Med. 75: 593-610, 1942. Puck, T. T., Robertson, O. H. and Lemon, H. M. The Bactericidal Action of Propylene Glycol Vapor on Micro-Organisms Suspended in Air. II. The Influence of Various Factors on the Activity of the Vapor. J. Exper. Med. 78: 387-406, 1943.

persed into the test room. Triethylene glycol vapor in bactericidal concentrations is not detectable in the air and is nontoxic.²⁷ Practical tests of this method have been delayed because of the lack, until recently, of adequate vaporizing apparatus and the need for an automatic control of the concentration of glycol vapor in the atmosphere. Two types of glycol vaporizers have recently been developed²⁷ and an apparatus for regulating the amount of glycol vapor in the air (glycostat) has now been devised.²⁸ With this necessary equipment it has been possible to initiate certain preliminary studies on the effect of triethylene glycol vapor on a specific disease agent present in the air under natural conditions, namely the hemolytic streptococcus. It was found that the continuous vaporization of glycol into wards housing patients with acute hemolytic streptococcus nasopharyngitis resulted in a pronounced reduction in the numbers of air-borne streptococci as compared with cultures of the air made before and after the periods of vaporization. That complete sterilization of the air was not achieved can be accounted for on the basis of certain factors which limit the activity of the glycol vapor, one of the most important being atmospheric humidity. Tests in the laboratory showed that a certain amount of moisture in the air was essential. Relative humidities of 40 to 60 per cent were optimum for the germicidal action of the vapors. With the humidity below 30 per cent little effect on dried bacterial particles was observed, although freshly atomized cultures were killed at much lower humidities. The bacterial particle must contain or acquire a certain amount of moisture before it will attract and hold a sufficient number of the glycol molecules so that a lethal concentration of this substance accumulates around the bacteria. Furthermore, dried bacteria such as are dispersed into the air from surfaces require a certain period of time, ten to twenty minutes, to become adequately moistened even in an atmosphere of 40 per cent relative humidity. Thus in wards such as those we studied, where streptococci were being constantly dispersed from secondary reservoirs, one would not expect to be able to keep the air completely free from streptococci with glycol vapor.

In view of these facts it seemed likely that a combination of dust-lint control measures and glycol vapor would result in more pronounced effect than could be secured with glycol vapor alone. This proved to be the case. Whereas triethylene glycol vapor in the absence of dust control caused a reduction of about 70 per cent in the number of air-borne streptococci as compared with the control periods, vapor in wards with treated floors and oiled bedding brought about a reduction of over 90 per cent.

While studies on glycol vapor could be carried out in hospital wards at satisfactory humidities by means of introducing into the atmosphere sufficient steam from the radiator system, such means of humidification are not available for tests of glycol in barracks, where the relative humidity in many localities in winter time is very low. The introduction of a large amount of water vapor with the glycol might be the solution to this problem in climates of moderate dryness. Other methods of humidification of barracks are under study. Among

the many phases of this subject still to be investigated is that of determining the minimum relative humidity at which a known continuous concentration of triethylene glycol is effective. With the glycostat available this will be possible to determine. It is not unlikely that a relative humidity which is below the optimum for germicidal action on dried bacterial or virus particles would still be highly effective for freshly expelled droplets of infected secretions.

The only published data on the use of glycol vapors for the control of acute respiratory disease are those of Harris and Stokes²⁸ who observed a considerable reduction in the incidence of colds and other infections of the upper respiratory tract in children occupying wards treated with propylene or triethylene glycol vapor as compared with untreated wards.

COMMENT

The reader may well question the assumption implicit in the latter part of this presentation, having to do with control measures, that the greater proportion of upper respiratory tract infections are acquired in the barracks. It must be granted that definite information on this point is lacking. However, there is a good deal of evidence in support of the view that certain specific diseases are spread principally in sleeping quarters. One of the most informative studies of this subject was made by Dudley²⁹ in 1920, who found in a group of boys, part of whom lived in dormitories and part of whom slept in dispersed quarters outside, that, although all the boys ate together and mixed intimately during the day, an epidemic of scarlet fever and diphtheria affected only those living in the dormitories. Our own observations cited earlier in this study of several instances in which a number of cases of hemolytic streptococcus infection of a single type occurred in barracks heavily contaminated with this micro-organism strongly suggest that these infections were acquired in the barracks. Other accounts of similar episodes, though less carefully studied, support the inference that, at least where the disease rate of these particular infections is high, sleeping quarters constitute an important focus of dissemination. No information is available concerning the proportion of respiratory infections acquired inside and outside the barracks. The usual scattering of cases of the so-called common respiratory disease is generally considered to indicate that most of these infections are acquired by outside contact. Likewise where sporadic cases of streptococcal disease are occurring, no definite locus of infection is evident. Yet further investigation, such as the results of dust control measures in barracks, may show that a considerable percentage of respiratory disease, in general, is communicated in the environment of the sleeping quarters where the soldier spends the greater part of his indoor life and where conditions for accumulation and dispersal of disease agents are optimum.

We wish to point out that the fundamental ideas for the control of the secondary reservoirs of disease agents were proposed by the English workers. Thomas⁷ found that oiling floor and bedclothes resulted in a 90 per cent reduction of air-borne bacteria in a hospital

ward, approximately the same result obtained by us in army barracks. Recent observations by Krueger and his associates³⁰ have corroborated the findings of others that oiling the floors alone brings about a substantial diminution in the number of air-borne bacteria in hospital wards. Also Feasby and Bynoe³¹ of the Canadian army have reported a reduction in the number of cases of hemolytic streptococcus infection coming from barracks in which oiled sweeping compounds were used, as contrasted with barracks lacking this means of dust control. We have been able to carry the oil preparation of bedclothes to the stage of practical application and hence test on a large scale the effectiveness of this means of reducing the incidence of air-borne infection.³² Furthermore, the results of our studies on the distribution and control of certain disease agents in the environment have shown that maximum diminution in the number of air-borne pathogens is brought about by means of aerial disinfection combined with measures for effective dust prevention.

SUMMARY

During the past two and one-half years the Commission on Air-Borne Infections, Board for the Investigation and Control of Influenza and Other Epidemic Diseases, Preventive Medicine Service, Office of the Surgeon General, U S Army, has been conducting studies on the transmission and control of acute diseases of the respiratory tract in the laboratory and in the field. Before effective measures for control could be devised, it was necessary to acquire much more information concerning the nature of air-borne infection. Investigation of the sources of air-suspended pathogenic bacteria and viruses revealed the fact that environmental contamination by the diseased individual results in secondary reservoirs of infectious material, in bedding and floor dust, from which desiccated secretions are redistributed into the atmosphere in particulate form. Extensive studies of environments containing hemolytic streptococcus patients or carriers have shown that bed-making and dry sweeping result in a pronounced increase in the numbers of streptococci in the air and probably constitute a more important source of aerial contamination than do "droplet nuclei" expelled directly from the infected person. The finding that hemolytic streptococci may survive for long periods of time (many months) in contaminated blankets added increased significance to the importance of bedclothes as reservoirs of infectious agents. Numerous observations on the relationship of air-borne hemolytic streptococci to the occurrence of streptococcal infection indicated that there was a definite association between the numbers of a given type of hemolytic streptococci present in the air and the incidence of infection with that type.

These findings provided the basis for the institution of certain measures designed to control air-borne infection by (1) preventing the dispersal of infectious mate-

rial into the air and (2) reducing the infectivity of contaminated atmospheres by killing the disease-producing agents in the air. The first of these measures consisted in oiling the floor and treating the bedclothes with an oil emulsion. Studies of the bacterial population of such treated environments, wards and barracks showed a striking reduction in both the total bacteria and the numbers of hemolytic streptococci present in the air and other parts of the environment. A test of the effect of oiling floors and bedclothes in a large number of army barracks has been instituted and, while not of sufficiently long duration to permit statistical conclusions, the study has yielded data indicating a definitely lowered incidence of acute respiratory infections in soldiers occupying the oiled barracks as compared with the controls. For the further control of aerial contamination, triethylene glycol vapor has been employed. Studies thus far have been limited to hospital wards. It was found that the numbers of hemolytic streptococci in the air of wards housing patients with this type of infection could be largely reduced by the presence in the air of triethylene glycol vapor in bactericidal concentrations. Maximum reduction in air-borne streptococci was observed when oiling of bedclothes and floors was employed in conjunction with the glycol vapor.

ABSTRACT OF DISCUSSION

DR EDWARD BIGG, Chicago. Dr Robertson and his associates have presented a fundamental basis for an understanding of the problem of the control of cross infections. If it were possible to control the factors of primary source of infection, reintroduction of organisms from secondary reservoirs and to sterilize completely the atmosphere of living groups, one could prevent air borne infection. Since none of these procedures can be effected to the necessary degree, it would appear that a combination of such measures as are available offers the greatest promise in the prevention of infections transmitted by the aerial route. Dr Robertson has shown clearly the effect of dust control. For the past two years our group at Northwestern has been studying the use of triethylene glycol vapors as a means of air sterilization and its application to the control of air borne disease. During the past winter we had an opportunity to carry out a practical test at a military camp. We have developed apparatus for glycol generation and distribution and were able to maintain bactericidal concentrations of glycol and optimum relative humidity conditions in military barracks. The humidity problem was solved by the use of a vaporizer which introduced water vapor along with the glycol. Studies were made on three groups of 640 men observed for six week intervals and equally divided into test and controls, the former sleeping in glycol treated quarters, the latter in untreated dormitories. A simple overall dust control measure was used, namely the oiling of the floors in both test and control barracks. A reduction in air borne disease of 12 per cent was produced for the entire period, but statistics on the final seventeen days of the period showed a reduction of 64 per cent. Unfortunately a longer test period was not possible, so that more conclusive evidence could not be obtained. The incidence of hemolytic streptococci recovered from throat cultures of men exposed to the effect of glycol vapors fell dramatically in contrast to the control individuals. There was a definite prevention of spread of hemolytic streptococci in the test dormitories and practically complete abolition of these organisms from the air in the glycol treated spaces. More effective dust control measures as outlined by Dr Robertson used in conjunction with triethylene glycol vapors will bring about a significant reduction in those diseases which now present one of the greatest problems in both civil and military life.

DR C H RAMMELKAMP, Fort Bragg, North Carolina. The fact that respiratory disease may be spread by dust, lint from blankets and similar vehicles needs to be emphasized, since it has been a common teaching that direct contact, contact with

32 After this paper had been sent in for publication we received the May 6 issue of the British Medical Journal which contained two papers, one describing a new formula for the oil treatment of bedclothes and the other its use in a study of the control of air borne streptococcal infection in hospital wards. Harwood, F. C., Ponney, J., and Edwards, C. W. Brit M J 1: 615, 1944. Wright, J., Cruickshank, R., and Gunn, W. Ibid p 611. And on page 616 of the same issue Anderson, P. H. R., Buchanan, J. A., and MacPortland, J. J. reported a reduction in incidence of acute respiratory disease occurring in barracks with oiled floors.

contaminated articles and droplet transmission, are primarily responsible for the spread of respiratory infection. Dr Robertson's data amply emphasize the importance of dust and blankets in the transmission of streptococcal infection and, in all probability, in the spread of other types of respiratory disease. During the past two and a half years the Commission on Acute Respiratory Diseases now established at Fort Bragg, North Carolina has been studying the problem of respiratory disease in the Army. During this period special emphasis has been placed on methods for determining the incidence of infection by the development of clinical and epidemiologic techniques as well as by studying etiology. With the exception of outbreaks of influenza, the big problem in respiratory disease in the Army lies in the high incidence of illness of unknown cause. Respiratory disease due to known and recognizable bacteria and viruses accounts for a relatively small proportion of the total cases of illness. Moreover, the incidence of total as well as undifferentiated respiratory disease is much greater in new recruits than in seasoned men; the approximate ratio in these two groups being 10 to 1. It has been repeatedly observed that when new recruits are brought together for the first time under the conditions of army life an epidemic of undifferentiated respiratory disease occurs consistently between the second and fifth weeks of army experience. This pattern of epidemic behavior has been quite constant, although the peak of the epidemic has reached higher levels in the winter than in the summer, in accordance with the known seasonal variation of total respiratory infection.

DR FRANCIS G. BLAKE, New Haven, Conn. There are as Dr Robertson pointed out, two potential sources of the spread of infection, that is the individual who himself is a dangerous disseminator of respiratory bacterial agents and the environment as represented by contaminated bedclothes and dust. It is highly important to define, if possible, by the experimental approach what is the relative importance of these two factors in the actual spread of epidemic disease. I don't know whether Dr Robertson plans to approach this problem by having a unit in which the bedclothes and floor are contaminated heavily with hemolytic streptococci, introducing into that unit a group of individuals who are shown not to be carriers of hemolytic streptococci, and a comparable experiment in which the floors and the beds are not contaminated, in which a dangerous human carrier is introduced. Such an experiment might serve to differentiate between the importance of these two possible sources of spread.

DR TRUMAN S. POTTER, Chicago. The beginning of a line of attack on disease as revolutionary as Dr Robertson's fully warrants our looking even above and beyond the facts actually in hand. Dr Robertson has been working chiefly on military diseases and for that reason has been constrained to bypass some of the problems which are of less pressing importance. I have been at the University of Chicago this last winter working in a different laboratory from Dr Robertson, and I have begun a few brief experiments on the tubercle bacillus. The tubercle bacillus has a much higher lipid content than most bacteria and consequently it could not be taken *a priori* that the glycols would be equally effective in penetrating this organism. Also there are certain facts in the epidemiology of tuberculosis which are quite different from those of other diseases. The organism is commonly encased in sputum, and the associated mucus might be expected to protect it in a measure, from the action of the glycols. Even now it certainly would be premature to speak of the actual significance of the practical prevention of disease, yet I want to say that it has been my privilege in the last winter to do a few brief experiments on the tubercle bacillus which show that this organism also can be killed both in the test tube and in the air with both propylene and triethylene glycol. In some of these experiments the bacilli were atomized into the test chamber containing the glycols, from a suspension of saliva and were thus coated with a thin film of mucus, as under natural conditions. The result, as determined by the guinea pig inhalation test was that the bacilli were again exterminated. We have, in the glycols, agents which are broader in their action than the sulfonamides. Although purely preventive and not curative in action, I feel that, in the long run the glycols may well strike us as having human importance equal to that of the sulfonamides or even greater.

ENURESIS

THE USE OF CYSTOURETHROGRAPHY IN DIAGNOSIS

M. LEOPOLD BRODNY, M.D.
AND
SAMUEL A. ROBINS, M.D.
BOSTON

Our primary purpose in this report is to evaluate cystourethrography as a method for investigation of organic uropathy in enuretic patients. The satisfactory presentation of this objective is dependent on a clear conception of the etiology of enuresis. It will therefore be necessary to interpret and clarify the various causative factors which constitute this problem.

Urinary continence is dependent on four factors:

1. An intelligence quotient adequate to appreciate the social necessity and hygienic desirability of controlling the time and place of voiding.
2. Proper and sufficient habit training to condition urination and voluntary control.
3. The patient must be free of specific neurotic and psychotic symptoms and have an emotional status consistent with his age group.
4. A normal voiding mechanism is essential for normal function. In the child, the anatomic and physiologic development must be accordant with the chronologic age.

Urinary continence may be maintained even though one or two of these components are deficient, provided there is a superior compensatory factor. The following illustrates the counteraction of these forces:

A. The mentally deficient. Persons with a very low intelligence quotient may be continent. It is possible to teach the feeble-minded person to be dry by inaugurating unusual conditioning reflexes. Similar techniques are used in house breaking animals.

B. Inadequate habit training. Many children without formal habit training develop continence. Their acute intelligence and emotional maturity sets up self-conditioning reflexes.

C. Emotional disturbances. An emotionally unstable person may by proper habit training maintain urinary continence. This is accomplished by active deconditioning or antagonistic reconditioning of the psychogenic factors involved.

D. Organic disease. The establishment of continence in an enuretic person does not rule out the presence of an organic lesion. Dryness may be maintained in the presence of pathologic structure and function by exceptional cerebral and emotional control or by suitable habit training.

It is not generally recognized that bed wetting and persistent nocturia in children are related and may replace each other. The former is an involuntary, the latter a voluntary reaction to similar stimuli. Their interchangeability depends on the efficiency of the factors of continence. Many parents disregard this nocturia in children. The blame for frequent voiding during the night is often placed on "overindulgence in fluids," "sleeplessness" or "weak kidneys." It is generally believed that the child will outgrow this condition. Unfortunately, some physicians have a similar attitude.

Read before the Section on Urology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.
Lieut. Comdr. Philip Solomon made it possible to study the enuretic patients from the Habit Clinic for Child Guidance, Douglas A. Thomas, M.D., Director.
From the Departments of Urology and Roentgenology, Tufts College Medical School, the Beth Israel Hospital, the Boston Floating Hospital, and the Boston Dispensary.

They consider a patient with enuresis is cured when the bed is dry even though he may void in the lavatory two to three times during the night. The same criteria for the cure of enuresis are also found in many reports in the literature.

Enuresis is caused by disturbance of one or more of the factors on which urinary continence is dependent. On this basis enuresis may be divided into four main types.

1 *Intellectual*—In this group are those enuretic persons whose intelligence quotient is insufficient to acquire new habits. Examples are found in mentally ill and defective children.

2 *Conditioned Reflex*—In this group enuresis is due to behavior problems and antagonistic habit reactions and is affected by environment, hygiene, social conditions and problem parents.

3 *Psychogenic*—This group consists of patients with psychoneurosis, psychopathic personalities, emotional disturbances and sexual disturbances.

4 *Organic*—This group consists of those enuretic persons with organic uropathy.

Combinations of the various types of enuresis occur. In fact, the majority of cases are not of a pure type. Enuresis of one type may agitate another type. The patient with primary organic enuresis often develops secondary emotional disturbances. The patient with a primary sexual disturbance may develop secondary organic changes in the prostate.

The proper classification of enuresis demands the investigation of the four factors of urinary continence. It is beyond the scope of this paper to discuss the first three factors. Their importance and relationship have been merely presented and stressed. More detailed discussions can be found in the psychological, psychiatric and psychosomatic literature.

Fig. 1 (a boy aged 3)—Normal cystourethrogram with Visco Ravopake. The bladder and urethra are clearly outlined. The opaque medium is well distributed and mixed with the urine. Note the sharpness of the ovoid area produced by the verumontanum in the posterior urethra between the constriction of the internal and the external sphincters.

The fourth factor, organic disease, plays an important role in the etiology of enuresis. Campbell¹ found uropathy in 60 per cent of 532 persistent enuretic patients whom he investigated. In spite of this unchallengeable finding, some physicians discourage urologic

investigation. The following is typical and was published less than two years ago—“Some methods to avoid”¹ “Manipulations or operations for enuresis such as cystoscopy, tonsillectomy, circumcision and the like. These operations are essentially irrational, except in very rare instances and often are taken by the patient

Fig. 2 (S. S., a boy aged 10 enuretic)—The bladder is hypotonic, slightly enlarged and irregular in contour. The base of the bladder is low and pouched. Note the concave defect at the upper border of the bladder (A) which is due to incomplete filling. The pressure is produced by the sigmoid and is often associated with improper bowel habits.

as being punishment for the enuresis.” Such a policy if applied to other symptoms becomes absurd.

The Children's Bureau² of the U. S. Department of Labor has made the following recommendation: “If a child as old as 3 years has the habit of wetting the bed, consult the doctor and have him give the child a careful examination.” This age is too young and we agree with Campbell that children under 4 years of age seldom require urologic examination solely because of enuresis.

How far shall this examination go to rule out organic disease? Certainly a general physical examination and urine analysis are indicated. The bladder and urethra should be investigated, but cystourethroscopy, which is customarily employed, is not simple and there are many factors which deter its wider use. Endoscopy in children usually requires an anesthetic, and there is reluctance among parents and physicians to submit the child to what they consider a major procedure. The examination necessitates special instruments and an observer with experience in pediatric urology. These facilities are often not available.

Cystourethrography is unhampered by these difficulties and is adequate for the routine investigation of enuretic patients. This is a simple office or dispensary procedure which can be carried out without a general anesthetic. It is safe and relatively free from reaction. The size, shape, position and abnormalities of the bladder and urethra are accurately visualized, and progression or retrogression of lesions can be observed and compared.

INDICATIONS FOR CYSTOGRAPHY AND URETHROGRAPHY IN THE ENURETIC

Enuresis is often empirically labeled as functional, and we believe this practice is contrary to the welfare of the patient. Every case of persistent enuresis should have a cystogram and urethrogram to rule out organic disease. This simple and safe technic should induce a

¹ Campbell M. F. Enuresis. Arch. Pediat. 54: 187-197, 1937.

greater number of physicians to submit children with enuresis to urologic investigation

Opaque Mediums—It has been our practice to use a 25 per cent solution of sodium iodide for cystography and Lipiodol or Iodochlorol for urethrography. The

Fig 3 (R. B. a boy aged 6)—Enuresis since birth. The base of the bladder is pouched with a wavy outline of the lower and lateral borders. The changes in the bladder are due to a congenital anomaly and edema secondary to infection.

former solution has given satisfactory results, while the latter has many disadvantages.⁴

In recent months we have employed a new substance called Visco-Rayopake, which is superior to the oils for urethrography and cystography. Rubin⁵ previously described the properties of this medium and reported its use for hysterosalpingography. Visco-Rayopake contains 3 per cent of a "viscosity base" (a polymeric form of polyvinyl alcohol) and 50 per cent of an opaque organic chemical (2, 4-dioxo-3-iodo-6-methyl tetrahydropyridine acetic acid) rendered soluble by the addition of 17 per cent diethanolamine.

Fig 4 (W. M. a boy aged 9)—Diurnal and nocturnal enuresis. Large atonic bladder with a tolerance capacity of 350 cc. Neurologic examination was negative. Diagnosis: spina bifida occulta with neuromuscular vesical dysfunction.

We have used Visco-Rayopake in over a hundred and twenty-five examinations with excellent visualization of the bladder and urethra.⁶ This medium is well tolerated

by children, flows easily and gives a homogeneous shadow with sharp outlines. The opacity can be reduced by diluting the Visco-Rayopake with water. The medium does not break up into globules when mixed with bladder urine (compare figure 1 with figure 9). Instruments and catheters are easily cleansed with warm water following their use. It does not destroy rubber or support bacterial growth. Visco-Rayopake is especially valuable for voiding urethrograms. It can be easily voided in a steady stream and still cast a shadow with sufficient opacity for rapid exposure (fig 5). Visco-Rayopake will be the subject of a more complete report at a later date.

CYSTOGRAMS

Cystography is considered a useful diagnostic procedure in adults, but its value in children has not been generally recognized. Campbell⁷ emphasized its merits

Fig 5 (R. R. a boy aged 12)—Nocturnal enuresis since birth. A, voiding cystourethrogram, anteroposterior view. B, cystogram. C, voiding cystourethrogram, oblique view. D, retrograde urethrogram, oblique view. The bladder outline is round and the edges are serrated by trabeculations (B). In the contracting state the bladder elongates vertically and narrows horizontally (A) and the detrusor descends retracting the posterior lip of the vesical neck (C).

when he wrote "properly interpreted these changes in the vesical outline are frequently sufficient to establish the correct diagnosis without further instrumentation." We have followed his cystographic technique.⁸ The ease of execution and the informative potentiality make cystography especially useful in the enuretic.

The position of the child's bladder is central and well above the upper border of the symphysis. The normal bladder in the child is elliptic (fig 1) or spherical when completely filled. When incompletely filled it appears flattened on the top (fig 2 A). In the oblique view the cystogram appears elongated in the horizontal diameter. Normally the cystographic outline is smooth. In the presence of chronic infection and obstruction the borders are irregular and the bladder wall is thickened (fig 11).

The appearance of sacculations or diverticula is similar to those in the adult bladder

Increased bladder capacity is a common finding in the enuretic. The atonicity is due to decompensation of the bladder musculature secondary to urethral obstruction or to defective nervous conduction, which causes sympathetic imbalance or diminished sensation to distention (somatic disturbances). The cystogram reveals an immense bladder shadow which is smooth and regular in outline and fills the entire pelvis (fig 4). A dilated bladder is of especial importance in spina bifida occulta. Bohart⁹ found 161 cases of spina bifida occulta in 931 symptomless spines, indicating that it is not a disease in itself but a normal deviation of the spinal column. The condition is of clinical importance only if it is associated with changes in the roots from the sacro-lumbar cord. A cystogram and urethrogram will determine whether there is any vesical involvement.

Diminished bladder capacity (hypertonicity) is due to vesical and urethral inflammation or to parasympathetic imbalance. The bladder shadow is small and irregular

Fig 6 (R I a boy aged 4½) —A retrograde urethrogram. B voiding urethrogram. Enuresis since birth. There is a constriction of the bulbous urethra. Constriction of the vesical neck and collicular edema. Note the proximal dilatation of the prostatic urethra (B) and the distal distention of the penile urethra (A).

in outline. Cystography in these irritable bladders may be unsatisfactory because of a rapid expulsion of the medium even when a small amount is used. We have observed severe bladder spasm and leakage around the catheter after the injection of less than 50 cc.

Normally the bladder base is curved with the convexity downward. Vesical neck hypertrophy or prostatic enlargement may protrude into the bladder and distort the base, so that there is a concavity downward (fig 7). Pouching is sometimes observed at the base, resembling a small cystocele (fig 3). The vesical outlet is not seen on the cystogram, but if the internal sphincter is paralyzed the opaque medium leaks into the posterior urethra, giving the appearance of a smooth funnel.

Ureteral reflux is not often observed in enuretic patients but, when present, indicates definite pathologic change. In these cases studies of the upper urinary tract are indicated.

URETHROGRAMS

Urethrography in children has been neglected. A careful search of the urologic and roentgenologic literature did not reveal a single report which completely covered this subject. The interpretation of urethrograms in children is too extensive for this paper and will

be presented at a later date. However sufficient description and explanation is introduced to appraise the value of the procedure in the enuretic. Correct interpretation of urethrograms requires correlation with cystoscopic operative and postmortem findings. When sufficient

Fig 7 (B C a boy aged 5) —Enuresis since birth. Note the elevation of the bladder base, the spasticity of the external sphincter and the enlarged rounded collicular shadow bifurcating the urethra.

experience has been gained, urethrography will be found as valuable for the study of lower urinary tract disease as pyelography is for the diagnosis of renal pathologic conditions. The technic of urethrography and a specially designed instrument to facilitate this procedure have been previously reported by one of us.¹⁰

Urethral Obstruction—Urethrography is especially valuable to demonstrate strictures of the anterior urethra in children. The small caliber of the canal makes routine urethroscopy difficult and unsatisfactory. On the urethrogram the constriction appears as a narrowing in the continuity of the canal. The secondary changes are also dramatically pictured. On the voiding

Fig 8 (R M a boy aged 6) —Diurnal and nocturnal enuresis. Patient has spina bifida occulta. Urethrogram reveals multiple organic lesions. There are two strictures in the glandular urethra. One is acquired and is at the meatus. The other is a congenital narrowing in the region of the fossa navicularis. Both the internal and the external sphincters are relaxed. The verumontanum is absent.

urethrogram a ballooning of the canal is observed proximal to the stricture, visualizing the distention and stasis caused by the obstruction. On the retrograde urethro-

gram the stricture impedes the flow of the injected medium and may produce mechanical distention distal to the obstruction (fig 6)

Stenosis of the glandular urethra is a common finding in the enuretic. Stockwell and Smith¹¹ found an incidence of 23 per cent and Winsbury-White¹² 27 per cent. The constriction is of two types on the urethrogram: one type is of the pinpoint variety and is a simple cylindrical stricture of the lips of the meatus. It is due to scarification secondary to a meatitis and is most common in the circumcised patient. The other type is a uniform narrowing extending from the meatus through the entire portion of the glandular urethra and is congenital in origin (fig 8). Occasionally the stenosis is so tight that filiform dilation is necessary before a catheter can be passed. On the voiding urethrogram narrowing of the stream at the stricture can be observed.

Local congenital malformations and acquired obstructions of the vesical outlet are types of deformities too often unrecognized in enuretic children. Hypertrophy of the internal sphincter (fig 9), contracture of the vesical neck (fig 6), median bar and congenital valves can be diagnosed by urethrography. These lesions disturb the architecture of the posterior urethra in relation to the bladder base. In hypertrophy of the internal sphincter the supracollicular portion of the urethra is elongated and compressed, forming a collar-like structure which by projecting into the bladder concaves the outline of the base. In contracture of the vesical neck the region of the internal sphincter is shortened and

neck. Median bar hypertrophy is best recognized in the oblique views and appears as a notching and elevation of the posterior lip at the urethrovessical junction.

Congenital valves of the posterior urethra occur in enuretic patients. The symptoms are usually those of

Fig 10 (H. M., a boy aged 9).—The base of the bladder is flattened and the vesical neck is constricted. The collicular shadow is bifurcated. The external sphincter is spastic and there is a meatal stenosis.

Fig 9 (D. L., a youth aged 18).—Urethrogram with 28 per cent lipiodol. Enuresis since birth. Arrow points to large cyst at the verumontanum. The vesical neck is elongated and tight and the external sphincter spastic. Enuresis was cured by endoscopic fulguration and urethral dilation.

constricted and the bladder base is flattened. On the voiding urethrogram the supracollicular portion of the urethra fails to dilate, owing to the rigidity of the vesical

obstruction, but enuresis may be the chief complaint. Campbell operated "on 9 boys whose valves were discovered during a urological examination for which persistent enuresis was the indication." Early urethrographic examination is essential, since the prognosis is dependent on the removal of obstruction before back pressure has produced irreversible renal damage. On the urethrogram a typical supracollicular funnel-shaped dilatation and bifurcation of the canal is observed. The effects of back pressure are evident above the obstruction. A discussion of the cystoscopic, postmortem and urethrographic findings in congenital valves has been previously reported by one of us.¹³

Abnormalities of the verumontanum occur in children and may often cause enuresis. Hypertrophy of the verumontanum may be congenital in origin and cause symptoms of obstruction. A congestive type of enlargement is seen in chronic masturbators. Verumontanitis due to infection is more apt to occur in the older enuretic patients and is associated with prostatitis (fig 7). The normal verumontanum projects into the lumen of the posterior urethra and appears in the contrast shadow as an elliptic area of diminished density (fig 1). With disease, this collicular defect is two to three times normal in size, it is round or pyriform and the outline is irregular (fig 10). Polyps, cysts (fig 9) and edema cause characteristic distortions of the shadow. Occasionally the verumontanum is absent on the urethrogram (fig 8). This may be a congenital anomaly or due to hormonal deficiency. These patients should be examined from an endocrinologic point of view.

Infections—Chronic and congestive prostatitis is recognized by characteristic changes in the posterior urethra (fig 12). On the retrograde urethrogram there can be noted compression and narrowing of the canal, enlargement of the verumontanum and elevation of the bladder base. In the presence of urethritis the outline of the anterior urethra is wavy, the channel is

narrower than normal and the external sphincter may be spastic. On the voiding urethrogram there is noted rigidity of the lumen of the posterior urethra.

Neuromuscular Dysfunction—Enuresis is often associated with imbalance of the detrusor and sphincteric musculature of the bladder. The etiology of this dysfunction is diagnosed by correlation with concomitant neurologic signs and symptoms. However, in many enuretic patients the disturbances of vesical innervation are the only evidence of a neuromuscular disease. Therefore normal neurologic findings in a child do not eliminate the possibility of neuromuscular uropathy.

The vesical dysfunction results from either congenital or acquired lesions of the spinal cord or peripheral nerves. Roentgenologic examination can disclose which muscular elements of the bladder or urethra are involved and whether they are spastic or parietic. The secondary changes due to infection and back pressure can also be observed.

The urethrogram visualizes the state and tone of the vesical sphincters. A spastic internal sphincter causes an hour glass deformity between the urethra and the bladder (fig 10). An atonic internal sphincter appears as a funnel shape dilatation of the supracolicular urethra. When both sphincters are atonic, the normal constrictions at the vesical neck and membranous urethra dilate and the prostatic canal appears as an undifferentiated tube (fig 8).

CONCLUSIONS

1 The intellectual, the conditioning, the psychogenic and the physical factors should be investigated in every patient with persistent enuresis over 4 years of age. Several etiologic factors may coexist.

Fig 11 (I. F. a boy aged 10)—Diurnal enuresis. The outline is wavy and scalloped because of trabeculations. The verumontanum is enlarged and edematous. The vesical neck is constricted.

2 The conversion of enuresis to nocturia does not constitute a cure.

3 A general physical and urologic examination is necessary for the diagnosis of organic uropathy in enuretic persons.

4 Cystourethrography should be part of this routine urologic examination.

5 Visco-Rayopaque is a superior contrast medium for cystourethrography.

6 Cystourethrography provides a graphic record of pathologic structure and function of the bladder and urethra.

Fig 12 (J. B. a boy aged 16)—Intermittent enuresis chronic masturbator for four years. The prostate was large and boggy. The lateral lobes projected into the bladder and compressed the prostatic urethra. The verumontanum was elongated. The external sphincter was spastic.

7 This simple and safe procedure should induce a greater number of physicians and parents to submit enuretic patients to urologic investigation.

ABSTRACT OF DISCUSSION

DR. GEORGE H. EWELL, Madison, Wis.—The paper presents a study of many points about the anatomy and physiology of children's bladders about which I was little aware. It calls attention to the fact that there are many different causes of enuresis and that local causes are responsible in the vast majority of them. I believed that enuresis was a behavior problem and that whenever you were consulted by one of these patients you promptly sent him back to the pediatrician, provided, of course, that the urine did not show gross evidence of infection or x-ray examinations did not show those common and gross conditions such as stones, hydronephrosis or other congenital abnormalities. The authors are describing children. I have done cystoscopies on a fair number of children with enuresis, both boys and girls. The majority of the cystoscopies that I have made have been on girls, because they are more readily examined. The vast majority of cases of enuresis in girls I have found to be due to inflammatory changes about the bladder neck and in the urethra. I am a believer in Folsom's studies and I approach the subject in the female from that point of view. I know that some of these cases are due to metabolic disturbances and we certainly know that feeble-minded children have enuresis. I have treated feeble-minded patients with enuresis and have relieved them. I believe that if Brodny and his associates and others will continue urologic investigation of cases of enuresis they will put the problem back where it belongs—in the hands of the urologist and not in the hands of the pediatricians or the so-called child guidance clinics.

LIEUTENANT COLONEL DORRIN F. RUDNICK, M. C., U. S. Army. In the Army we do not feel that enuresis is necessarily a habit. It is far more frequently a symptom of an underlying physical or mental condition. We are able to classify most cases in the following groups: (1) organic disease, (2) psychoneurosis, (3) lack of proper training and (4) malingering. We have encountered cases that were a part of a systemic disease such as diabetes insipidus, hyperthyroidism and hypoparathyroidism. These represented a very small percentage and were controlled by treatment directed at the underlying condition. We were especially pleased with the improvement of 1 case under therapy with posterior pituitary injection. Organic lesions of the genitourinary tract have not been encountered as frequently as one would expect. In every case cystoscopy was carefully done and intravenous or retrograde pyelograms made. The lesion that we found consistently present, if any in the genitourinary tract, was an enlarged and sensitive verumontanum. This most frequently was found with a history of masturbation or chronic withdrawal. We feel that masturbation is elaborately indulged in. Whether the edematous, sensitive verumontanum is directly the result of masturbation or withdrawal or not, we are able to say that cauterization has produced a clearing up of the local situation and with its improvement a disappearance of the enuresis. Phimosis of varying degree of severity was encountered but circumcision failed to improve a single case in our series. Excessive acidity of the urine was not frequently found, and its correction was not followed by benefit. Limitation of fluid intake, abolition of fatiguing and exciting factors, position while sleeping and hospitalization have all been repeatedly tried without benefit. Dr. Rose suggested the central character of the stimulation and that it was initiated by a stimulus that resulted when urine arrived in the posterior urethra. This led to his suggestion of the application of perineal pressure. We have tried this in 1 case with good results. However, removal of the pressure after a few nights was followed by recurrence, so apparently a much longer period of reeducation or habit correction will be necessary. Malingering has accounted for a certain number of cases. Incurable enuresis results in a medical discharge from the Army, and each such discharge is usually followed by a series of other cases making their appearance at the clinic in the hopes of likewise getting out. These cases are not too difficult of segregation, however, and firm measures usually result in a rapid and thorough "drying up." The relationship of psychoneurotic and personality defect factors to enuresis is an all important one. Sixty-five per cent of the cases I have seen fall into this group. The cases practically always present a personality problem, unusual shyness or sensitivity, sexual repression or emotional instability. Infantile regression is a terrific problem in the Army, making its appearance in many different forms. The fainting, crying spells and refusal to eat manifested in so many cases is probably a comparable process to enuresis in these young men with personality defect complexes. The stress and strain of adjustment to the Army undoubtedly activates these processes. Adult enuresis is a problem chiefly for the neuropsychiatrist.

DR. REX VAN DUZEN, Dallas, Texas. I prefer cystoscopy to cystourethrograms. The latter have been inconstant in my hands. I feel that the usual cystoscopy is made too casually. A few years ago it was suggested that enuresis was a problem only for the pediatrician. The experiences of the armed forces has brought it forcibly to our attention that many adults are "bed wetters." I have recently seen a lady of wealth, aged 55, who has been partially incontinent throughout life because she had been told that nothing could be done. Because many feeble-minded patients are "bed wetters," the public has often associated bed wetting with low mentality. This has caused many to conceal the affliction for fear of the added stigma. We have all heard the statements that it would cease at puberty or when sexual relations were experienced. Some cases were cured at puberty or after marriage and were the basis for these conclusions. I am speaking of the persons who asked to consult you after office hours or behind carefully closed doors, the patient who feels it is a disgraceful condition or the one who is threatened with divorce. The recent suggestion of the use of ephedrine sulfate and methyl testosterone should be stressed. Ephedrine sulfate produces an apathy, and the usual stimuli from the bladder fail to produce the normal reflex action and usually

allow the bladder to hold the urine secreted during the night. Many boys have been cured by methyl testosterone. I believe its action is due to engorgement of erectile tissue about the urethra. However, one patient who was decidedly improved by ephedrine sulfate became totally incontinent when methyl testosterone was given and he was very slow to respond to ephedrine when it was resumed. In 1935 I resected the presacral nerve for enuresis, with complete and permanent cure. This has been duplicated in other cases. Presacral neurectomy produces a paralysis of the trigone muscle and these patients have to strain to start the act of urination. This has been sufficient to awaken the patient.

DR. GRAYSON L. CARROLL, St. Louis. The question of enuresis was placed on the program as a result of conversation with medical officers who are in army camps. I was amazed to discover the large amount of enuresis found in these camps. I thought that it was high time that we were finding out something about it, and we as urologists are charged with the responsibility. I found considerable difficulty in having some one write on the subject and to find discussers, because they all frankly admitted that they didn't know enough about it. The contribution of Drs. Brodny and Robins was a splendid one, and I think that out of this discussion will come some constructive ideas.

DR. MEREDITH F. CAMPBELL, New York. We are all agreed that enuresis is a functional condition in at least 95 per cent of the cases. Yet it has been my observation in the study of over 1,500 enuretic children subjected to urologic examination because intensive medical treatment had been ineffectual that organic urologic disease existed in 50 to 60 per cent. The disease is treated on the basis of the demonstrated uropathologic condition. Cystourethrograms effectively illustrate the desirability of carrying out complete urologic examination of enuretic individuals, particularly children, whom three or four months of intensive medical therapy, psychotherapy, gold stars, alarm clocks and atropine fails to cure of enuresis. A physician's son aged 8 years acquired gonorrhea at the age of 2. He had been casually examined by several pediatricians and by eminent urologists. He was said to suffer only a functional condition to be outgrown, but none of these clinicians took the trouble to investigate adequately the boy urologically. A urethrogram beautifully demonstrated the filiform caliber gonorrheal stricture of the bulbous urethra. Simple periodic progressive dilation of the stricture with steel sounds not only cured the enuresis but forestalled subsequent severe back pressure damage of the kidneys. Many cases of so-called enuresis will be found on adequate examination to be organic urologic disease. Here the enuresis is merely a symptom, and eradication of the organic disease almost always causes the bed wetting to cease.

DR. M. LEOPOLD BRODNY, Boston. We deliberately refrained from discussing the treatment of enuresis because our subject is primarily a diagnostic problem. A point we wish to emphasize is that the study of an enuretic person demands team work. Our organization is composed of a pediatric psychiatrist, a roentgenologist, a pediatrician and a urologist. We study these patients from four angles—the four factors of continence. Only in this manner can the patient be satisfactorily treated because enuretic persons with organic lesions may also have pronounced emotional disturbances. Consequently the patient may retain his symptom if only the organic condition is corrected. The enuresis remains on a functional basis. As for diabetes, Dr. Joslin informed me that his incidence of enuresis is no greater in the diabetic than it is in the normal child. One of our members inquired about the opaque medium we are using. It is an organic iodide in polyvinyl alcohol and was prepared by Hoffmann-La Roche. It is not yet available for distribution. Rubin has previously reported the substance for use in hysterosalpingography. It has a viscosity very similar to Lipiodol and can be diluted by the addition of water. This characteristic is very valuable for use in children because the viscosity and opacity can be controlled without the use of special oils. It takes a little experience and effort to be able to read urethrograms. However, after a period of cystoscopic correlation abnormalities are recognized, and the lesions can be diagnosed directly from the roentgenograms. Some of the lesions observed on the urethrogram cannot be detected by cystoscopy.

THE EFFECT OF PARA-AMINOHIPPURIC
ACID ON PLASMA CONCENTRATION
OF PENICILLIN IN MAN

KARL H BEYER, PH D, MD

HARRISON FLIPPIN, MD

W F VERWEY, D Sc

AND

ROLAND WOODWARD, BS

GLENOLDEN, PA

Since the original announcement by Beyer, Peters, Woodward, Verwey and Mattis¹ three reports have been submitted for publication or appear in the literature to the effect that when sodium para-aminohippurate and penicillin were administered simultaneously the former compound competed with penicillin for the same renal tubular excretory mechanism. By doing so the rate of renal elimination of penicillin was much reduced, thereby slowing considerably the rate of fall of the plasma concentration of the antibiotic agent. It was shown further that, in experiments wherein penicillin was administered continuously at a given rate for as long as forty-eight to fifty-four hours, raising or lowering the plasma concentration of para-aminohippuric acid similarly administered produced a concomitant elevation or fall of the plasma concentration of penicillin. A combination of these agents was administered continuously by venoclysis for forty-eight hours to dogs without producing functional or histomorphologic changes attributable to the two agents.³ Finally, it was shown that the acute toxicity of sodium para-aminohippurate was very low, being less than for sodium hippurate a metabolite.⁴

In view of the widespread interest in this research and the implications of the possible therapeutic efficacy of the combination, it was decided to obtain data on a few patients to determine whether the simultaneous administration of para-aminohippuric acid with penicillin did produce an elevated plasma concentration of the antibiotic agent. Such a program would also permit us to study the patients carefully for any untoward reactions to the therapy so that we might be able to call these effects to the attention of other investigators.

METHODS

Penicillin was administered continuously by venoclysis at a constant unitage and rate over a period of thirty hours. At the onset the patients were given a priming intravenous dose of 10,000 units of penicillin sodium and were then connected immediately to the "drip" infusion outfit. At the end of six hours the infusion solution was changed from penicillin in 5 per cent glucose to penicillin in 6 per cent sodium para-aminohippurate. At that time the tube was clamped

and 50 cc of 6 per cent para-aminohippuric acid was injected intravenously through the rubber tubing just above the needle adapter. This usually was injected over a period of ten minutes. The tube was then unclamped and the infusion was adjusted to the previous rate. Penicillin in para-aminohippuric acid was administered over a period of twelve hours, at the end of which time the infusion solution was changed back to penicillin in 5 per cent glucose for the remaining twelve hours of the experiment. Thus there were three phases to the test: an initial control (six hour) phase wherein penicillin was administered in glucose solution, a second (twelve hour) phase wherein penicillin was administered in a 6 per cent solution of sodium para-aminohippurate and a third or control (twelve hour) phase during which penicillin was administered again in glucose solution.

A blood sample was taken at the beginning of the test for control hematologic tests, at four and six hours in the first phase of the experiment at six and twelve hours in the para-aminohippuric acid phase and at six and twelve hours in the third period. The patients and the physical equipment were observed continuously by one or the other of the first two authors during the thirty-hour periods.

The penicillin plasma assays were performed by a modification of the Rammelkamp method.⁵ In the assays on the first 5 patients horse erythrocytes were used as the test object. Since human plasma contains lysins for horse erythrocytes, assays on plasma from the first 5 patients were complicated in the lower dilutions by spontaneous lysis. However, penicillin end points were determined satisfactorily by the microscopic demonstration of streptococcus multiplication. Human erythrocytes were employed quite satisfactorily in the assays on the last 4 subjects. The method for the determination of para-aminohippuric acid in body fluids was simply a modification of the conventional Bratton and Marshall procedure for sulfonamides and has been described in detail elsewhere.⁶

Patients were selected at random without regard to age, sex, severity of illness or diagnosis, except that it seemed best not to complicate the results by using any patient with primarily a renal disease. While the condition of the patients was carefully followed, we shall not attempt to evaluate the experiments in terms of therapeutic results.

RESULTS

The information and the results of the tests on 9 patients are summarized in the accompanying table. From these data other information may be calculated. Examination of the table reveals that in every instance the administration of para-aminohippuric acid with penicillin caused at least a twofold increase in plasma concentration of the antibiotic agent. Para-aminohippuric acid was effective in producing this elevation at its lowest plasma concentration which obtained in the experiments (79 mg per hundred cubic centimeters) but the greatest (over fivefold) accentuation of penicillin plasma concentration was in the case having the highest para-aminohippuric acid plasma concentration (477 to 469 mg per cubic centimeter). Thus there was a definite relationship between the plasma concen-

tration of para-aminohippuric acid within this range and the amount to which the penicillin level was elevated. A rate of infusion of about 80 mg per kilogram per hour appeared to be adequate to maintain a para-aminohippuric acid plasma concentration of 10 mg per hundred cubic centimeters or over when normal renal function was present.

A combination of circumstances tended to make the basal penicillin plasma concentration of the last 4 patients considerably higher than was anticipated from the earlier experiments in the first 5. These were the greater basal concentrations of penicillin contained in the solutions administered to patients of lighter weight, and certain differences in handling the plasma. However, there can be no doubt as to the quantitative changes within each test reflecting the effect of para-aminohippuric acid administered.

The second patient who received the same amount of para-aminohippuric solution at a rate of injection of 5 cc per minute also defecated within a few minutes after the injection.

After this experience of intestinal and bladder smooth muscle response to the injection it was decided to warm the solutions for the priming doses to body temperature before their administration and to inject the material over a period of ten minutes (5 cc per minute). After the initiation of this procedure there was only 1 patient (E. R.) who had a bowel movement immediately after the injection of para-aminohippuric acid. This patient also had a sensation of warmth during the injection, which promptly subsided following instigation of the penicillin-para-aminohippuric acid "drip." This was the only patient who had any subjective reaction to the injection. In several instances the change to para-

* Diagnosis: W. E. atypical pneumonia; J. J. asthma; A. W. tuberculous peritonitis; S. P. Hodgkin's disease; on Oct. January 1944; J. C. acute pharyngitis; bronchopneumonia; P. D. infectious mononucleosis; B. C. periostitis of femur; A. A. asthma; E. R. lobar pneumonia.

There was no outstanding difference in response due to age, sex, or race. It was not possible in so small a number of patients to note any difference in penicillin response to para-aminohippuric acid attributable to the nature or severity of the diseases, though these two factors varied widely in this series.

Pharmacodynamic Effects of Sodium Para-Aminohippurate—These should more properly be considered in two categories: (1) those effects attending the injection of the priming doses and (2) those occurring during or following the para-aminohippuric acid infusions.

The purpose of the initial intravenous administration of 50 cc of 6 per cent para-aminohippuric acid was to saturate the patients quickly and to attain satisfactory plasma concentrations which might be maintained by the subsequent infusions. The administration of the 50 cc volume of material over a period of five minutes to the first patient was followed immediately by defecation and micturition but was attended by no noticeable subjective manifestations. Since none of the patients appreciated that they were receiving anything besides solutions of penicillin, the psychic element in the subjective response to para-aminohippuric acid was mini-

aminohippuric acid, including the priming dose, was made at night during the patients' natural sleep without their knowledge of the procedure.

There was no instance of an objective or subjective reaction to the combined penicillin and sodium para-aminohippuric infusion either during or for several days following the twelve hour infusions other than what has been described to occur in certain instances following the initial intravenous injections. How much of this smooth muscle response following the priming dose was due to a reflex response initiated by the local cooling of the vein for five to ten minutes and how much could be ascribed definitely to para-aminohippuric acid was not certain. However, the sign which has been described was neither serious nor disagreeable. The combination of penicillin and para-aminohippuric acid therapy cannot be said to have influenced deleteriously the physical condition, the blood picture or the illness of any of the patients.

The patients were permitted to continue their regular therapy, to eat their customary hospital diet and to drink water or fruit juice whenever they liked. It should be pointed out that no source of electrolyte other than the para-aminohippuric acid, which has been

adjusted with sodium hydroxide to pH 7.0, was used in the infusion solutions and no edema was noted in any of the patients

COMMENT

The results of this research are presented herein simply to demonstrate that in man the intravenous administration of sodium para-aminohippurate is capable of elevating several-fold the plasma concentration of penicillin over that which obtains when the latter agent is administered by venoclysis in glucose solution. This was in effect a confirmation in the human being of what has already been found to obtain in dogs. For this purpose only a small number of patients was deemed necessary.

It was found that only when para-aminohippuric acid was administered rapidly at room temperature was there noted any objective or subjective reaction to the drug. The only noteworthy untoward effect occurred following the administration of certain of the priming doses of para-aminohippuric acid, and this was a contraction of the smooth musculature of the large intestine and bladder, unattended by pain or discomfort. The infusion of para-aminohippuric acid and penicillin continuously for twelve hours produced no discernible deleterious effects on the patients who manifested a number of unrelated disease entities.

It would appear from this and previous animal experimentation that, if attention is given to rate of fluid administration and electrolyte balance, one should anticipate no serious consequences to the administration of penicillin in such a solution of sodium para-aminohippurate over a much more extended period of time. It seems reasonable at this stage of our knowledge to suggest that the plasma concentration of para-aminohippuric acid be checked fairly frequently to make sure that the function of kidneys known to be diseased is sufficient to allow excretion of the drug rapidly enough to prevent the blood level of para-aminohippuric acid from becoming excessive. It is probable that should such a circumstance be found to occur the effectiveness of this combination might be greater than ordinarily would be expected at lower plasma concentrations of para-aminohippuric acid than those used in this work. In making this final suggestion we have in mind the observations of Rammelkamp and Keefer⁷ that more effective plasma concentrations of penicillin were found to be present in patients who had known renal involvement. This can be interpreted in the light of recent work⁸ as probably being due to renal damage wherein there exists a decreased transport capacity of the tubular excretory mechanism.

CONCLUSIONS

In human beings, as in dogs, one can either effect a considerable economy of penicillin or maintain plasma concentrations of the antibiotic agent not heretofore practicable when penicillin together with sodium para-aminohippurate is administered continuously by venoclysis. Very few secondary effects have been observed to attend the combined use of these compounds in this study.

THE MEDICAL MANAGEMENT OF
ULCERATIVE COLITIS

J. ARNOLD BARGEN, M.D.

ROCHESTER, MINN.

There are many different types of ulcerative colitis. All forms of ulcerative colitis assume in their very nature the status of chronic disease. Hence the term "chronic ulcerative colitis" is best used to denote general clinicopathologic syndromes rather than to designate one of the several specific disease entities in which these syndromes are present. In medical practice it becomes necessary to study chronic ulcerative colitis according to etiologic types, and the first and most fundamental clinical effort should be directed at determining the specific etiologic factor responsible for the development of the syndrome in a given case. The infection may be caused by one or more of several bacteria or animal parasites, in association with certain dietary and constitutional deficiencies, or by other conditions, some of them still unknown.

STREPTOCOCCIC ULCERATIVE COLITIS

The most common condition of the group involving primarily the large intestine is that commonly referred to as "nonspecific" or "idiopathic" ulcerative colitis. If physicians using the term would apply it to a single disease entity, well and good, but unfortunately a variety of ulcerative intestinal conditions are included under this designation. In fact, some writers include under it all cases of ulcerative colitis which are not of amebic or tuberculous origin. Consequently the term becomes no longer tenable. The terms "colitis gravis" and "thrombo-ulcerative colitis" are descriptive of the serious nature of the disease and its pathologic inception and go far in depicting a disease entity. However, since in this paper I shall aim to give definite status to each form of ulcerative colitis I shall refer to this type as streptococcic ulcerative colitis.

This disease has characteristic pathologic manifestations and hence typical proctoscopic and roentgenologic features. Its lesions begin in the most distal segment of the rectum, just above the anal canal. Diffuseness of involvement of the bowel is its pathognomonic feature. Whether 1 inch of the lower part of the rectum or 5 feet of bowel are involved, the involved segment always is affected in its entirety, its entire circumference and the deeper layers of the wall and the mucosa secondarily. This gives the granular, easily bleeding mucous membrane so characteristic of this lesion. The disease tends to spread upward until the entire colon, and even the lower part of the ileum in the late stages of the disease, become involved. Since it is primarily a disease of the intestinal wall, a very characteristic roentgenologic picture develops. The bowel becomes diffusely narrowed, haustral markings are erased, the flexures and curves become more angulated than those of the normal bowel and the result is a smooth tube. In this, streptococcic ulcerative colitis differs from all other forms of ulcerative intestinal disease, except perhaps regional enteritis when it is confined to the distal portion of the ileum. The latter condition has, however, many features to distinguish it from streptococcic ulcerative colitis. Because of the

Read before the joint meeting of the Section on Surgery, General and Abdominal and the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

relatively high incidence of the streptococcic form of ulcerative colitis and because of the consistency with which its clinical, proctoscopic and roentgenologic manifestations conform to a certain pattern, I am inclined to use this type of ulcerative colitis as a norm and to describe other types chiefly by noting in what respects they differ from it

This form of ulcerative colitis manifests itself in a variety of ways, but in general the clinical manifestations follow one of three general courses. When the lesions are limited to the lower segments of the large intestine, particularly the rectum and rectosigmoid, the onset of symptoms can be described as insidious. The patient may have normal motions of the bowel but in addition may pass two or three or many bloody, purulent rectal discharges. He may not have any other important systemic symptoms except that he will gradually begin to speak of not feeling well. His complaint of not feeling up to par may increase gradually as the number of rectal discharges increases and ultimately a mild form of diarrhea may develop.

The second common onset may be classified by saying that the symptoms are severe. The patient may start rather suddenly with bloody diarrhea, low grade fever and gradual loss of appetite and with them loss of weight and all the concomitants of a moderately severe illness. All the symptoms may start in a fulminating manner with an onset almost like that of lobar pneumonia or other similar serious illness. There will be a high fever, massive discharges of bloody material from the rectum, great prostration and rapid depletion.

A patient's symptoms may remain in the insidious form for months or years, and then at the time of an infection of the upper part of the respiratory tract some other intercurrent illness or perhaps some severe nervous trauma there may be a sudden exacerbation of the disease and a change to a severe or even the fulminating form.

The question is often raised whether these are different diseases or stages of the same disease. Experience seems to indicate that these are stages of the same disease attacking patients in various ways. Thus one must be ever on the alert for the occurrence of this disease in these several forms so that it may be distinguished carefully from the types of colitis which are to be discussed presently.

The treatment of this well defined entity is not as satisfactory as its clinical and pathologic picture might suggest. Nevertheless, if certain basic principles of therapy are followed the end results will usually be very gratifying. The disease is of the nature of a chronic destructive infection and so an adequate rest program must be devised. This may not necessarily mean rest in bed, for in the case of the milder types, in which the infection is confined to the distal segments of the large intestine, rest in bed would hardly be wise. Furthermore, the dictum that "disease below the diaphragm makes for pessimism" is well illustrated in this condition and therefore restful relaxation or a restful recreation is often more valuable than complete physical rest. However, when the disease advances to more proximal segments of the bowel so that diarrhea is severe, total body rest may be indicated. Reduction of intestinal peristalsis by any available means must be considered. Although minimal amounts of opium and its derivatives are indicated in selected cases, other sedative preparations and powders acting as adsorbents

will often do much to allay intestinal peristalsis and thus create intestinal rest.

The second important measure of therapy is to improve bodily resistance to a severe infection and to replace the tremendous losses of food, especially proteins and vitamins, sustained in an active diarrhea. Thus a diet rich in calories, proteins and vitamins and low in residue is desired, however, it may be necessary to approach this very gradually, because during the fulminating stages of the disease it is often necessary to withhold food by mouth entirely. It may be necessary to begin by feeding perorally, gradually increasing the food intake very cautiously until finally in the more chronic stages of the disease a diet based on the foregoing principles and containing well over 100 Gm of protein and extra amounts of vitamins is allowed.

Further protection against streptococcic ulcerative colitis is achieved by the cautious administration of an antistreptococcus vaccine. This can be given in increasing amounts, the injections being maintained always under the point of any local or systemic reaction.

Since most of these patients will come under the physician's observation after there has been considerable loss of blood, anemia will almost invariably be present and may reach profound degrees, and so the fourth method of combating the condition will be the administration of repeated blood transfusions. The average patient will tolerate a series of small transfusions, for example, 200 to 300 cc of blood, better than the larger amounts of blood commonly given, that is, 500 cc. The various preparations of iron commonly administered to patients suffering from the hypochromic type of anemia are so often intestinal irritants that, when used, they should be given in minimal amounts and administered with great caution.

Various drugs of the sulfonamide series such as azosulfamide, succinylsulfathiazole, sulfaguanidine and sulfathalidine have had ample trial in combating the active stages of streptococcic ulcerative colitis. So far, azosulfamide seems to be the drug of choice of this series for this type of colitis. The average amounts administered may range from 50 to 120 grains (3.2 to 8 Gm), given in divided doses daily.

Penicillin has not been given an adequate trial in the treatment of streptococcic ulcerative colitis nor is it reasonable to expect this substance to affect more than the severe septic phases of this disease.

The removal of foci of infection such as obvious infections in the tonsils and teeth is of prime importance in combating this infection. Many other measures will come into play in the management of the individual cases of this form of colitis.

TUBERCULOUS ULCERATIVE COLITIS

Although infection of the intestine by *Mycobacterium tuberculosis* is primarily of the small intestine, it will commonly involve both small and large intestine, and some recent evidence tends to substantiate the thought that primary tuberculosis of the large intestine may occur. In the average case tuberculous ileocolitis is secondary to tuberculosis of the lungs or tuberculosis elsewhere in the body. The ulcers of this disease will be distributed irregularly and associated with lesions visible on the serous surface of the bowel and with milary tubercles. The infection will commonly attack the ileocecal coil and only in the late stages will the lesions progress sufficiently caudad to be visible through the sigmoidoscope. Thus the roentgenologic examinations will be the essential diagnostic examinations and

will be featured by characteristic irritability with rapid emptying and filling of the ileocecal region, and great irregularity of the intestinal lesions will be observed in the roentgenogram. The smooth contour of the intestinal wall so commonly seen in cases of streptococcic colitis is not present in tuberculous ileocolitis because the disease involves more the mucosa than the wall of the bowel.

Although some chemotherapeutic agents related to the sulfonamide compounds, such as promin and promizole, bid fair to have value in the management of this disease, the accepted treatment is still adequate care in a sanatorium, this to include carefully regulated sun baths, a high caloric diet including especially large amounts of vitamin C in the form of such substances as tomato juice and a properly planned program of rest. Pneumoperitoneum and oxypertoneum have been found helpful in some cases. Roentgen therapy also has its advocates.

ULCERATIVE COLITIS DUE TO THE VIRUS OF VENEREAL LYMPHOGRANULOMA

A third form of ulcerative colitis in which the lesions are limited to the large intestine is that caused by the virus of venereal lymphogranuloma. Here again the lesions start in the rectum and distal segments of the large intestine. The disease is also of the wall of the bowel but involves not only the wall but the lymphatic structures around it and so there develops a condition in which a stiff tube having the feel and giving obviously the appearance through the proctoscope of perirectal inflammation exists. There may be multiple small sinuses from the mucous membrane to the deeper structures and so a rather definite proctoscopic and roentgenologic picture results. The disease will be limited to the rectum and rectosigmoid structures and the normal bowel will be reached much more abruptly than in the streptococcic variety. Almost invariably the patient will feel generally well and his complaints will be largely in reference to the local rectal condition. The diagnosis in this type of case will depend largely on the history of previous venereal infection, possibly the presence of buboes and among women very commonly the presence of preceding vulval lesions. The Frei reaction will be positive. But even if these conditions exist the diagnosis of colitis due to the virus of venereal lymphogranuloma is not tenable if characteristic lesions of the rectum do not exist.

It used to be said that "when a patient once has an infection by the virus of lymphopathia venereum he will always die with it but never from it." The advent of the sulfonamide compounds may well change this dictum. Sulfathiazole, succinylsulfathiazole and sulfaguanidine have been particularly efficacious in the treatment of this infection. The latter two because of their lack of toxicity and minimal systemic absorption have been particularly useful since they can be administered in fairly large doses over a long period. Ten to 15 Gm. of one of the drugs has been administered daily for weeks to several months in selected cases, with a gradual reduction of the bloody rectal discharges. The stools have even become soft to formed, approaching normality not only in their consistency but also in their numbers. The intestinal wall has become softer and more pliable and the rectal lumen has gradually enlarged.

AMEBIC ULCERATIVE COLITIS

Another type of colitis in which the lesions are limited to the large intestine is that caused by *Endameba histolytica*. Here the lesions are localized pri-

marily to the cecum and possibly the flexures of the large intestine, although the entire large intestine may be involved. If the disease has advanced sufficiently toward the rectum so that lesions are visible in its mucous membrane, they present a very characteristic appearance. The ulcers give the impression of being punched out, with raised edges covered by a fleck of mucus and a hyperemic zone around the individual ulcer. Between the ulcers the mucous membrane is relatively normal. The disease largely affects the mucosa instead of the wall, and there should be little difficulty in distinguishing this type of ulcerative colitis from the streptococcic variety of colitis. Consequently the symptoms are quite at variance with those of the streptococcic variety. Bleeding occurs relatively late in the disease instead of being present as one of the first symptoms. The severe prostration of the fulminating type of ulcerative colitis is observed rarely. The patient is usually in a relatively good condition.

Roentgenologic examinations too show a rather characteristic deformity of the large intestine when the disease is sufficiently advanced. However, even early in the disease there may be the characteristic features in the cecum, namely, some narrowing and irritability when no other colonic lesions exist. With the progress of the disease the cecum becomes coned or narrowed to a point and in the entire ascending colon may be narrowed irregularly. This is not a smooth diffuse narrowing such as one encountered in the streptococcic type of ulcerative colitis. As the rectum is approached there will be less and less roentgenologic evidence of disease except in those cases in which the greatest disease is at the flexures or in unusual segments.

Of all the forms of ulcerative colitis, the amebic is the most amenable to treatment. Without any additional supportive treatment, amebiasis can be controlled or perhaps cured in most instances by the properly timed administration of a suitable combination of preparations of ipecac, arsenic and iodine. A suitable program for the administration of these chemotherapeutic drugs is as follows: $\frac{3}{4}$ grain (0.043 gm.) of the active principle of ipecac, namely emetine hydrochloride, administered subcutaneously twice daily until 4 grains (0.26 Gm.) of the drug has been given. On the same day in which the emetine is given, 0.25 Gm. of carbarsone should be given three times a day and administered for four days. This is to be followed by 0.25 to 0.5 Gm. of diodoquin for seven days, and this in turn is to be followed by a second course of emetine and carbarsone. A series of stools should be examined after this for the trophozoites or cysts of *Endameba histolytica*.

CHRONIC BACILLARY DYSENTERY

There is a form of ulcerative ileocolitis which follows in the wake of severe bacillary dysentery due to one or several of the strains of *Shigella paradysenteriae*. The fact that this condition follows, although very occasionally, an epidemic of acute bacillary dysentery will in itself be suggestive of the diagnosis. However, in the final analysis the diagnosis will depend on the presence in the blood of agglutinins (in significant titer, at least 1:320 or higher) of one or several strains of *Shigella paradysenteriae*. The lesions of this disease will be irregular and disseminated. In the occasional case in which extensive destructive ulcerative disease occurs, secondary invaders may be responsible for the late lesions. When lesions are visible through the sigmoidoscope and irregular as far as size, extent and mucosal appearance are concerned, they are particularly

striking. It has been said that the lesions are characteristic because of their irregular yet extensive distribution. This impression is substantiated by the roentgenologic appearance of the bowel in these cases.

Just as in cases of acute bacillary dysentery, so also in cases of chronic bacillary dysentery the sulfonamide compounds, particularly succinylsulfathiazole and sulfaguanidine, have given very satisfactory results. In mild cases and those caused by organisms of the Sonne type the disease has responded well to large amounts of succinylsulfathiazole. In more severe cases and particularly those caused by the Flexner and Shiga strains of these organisms it has responded better to sulfaguanidine, given again in fairly large doses. Type specific serums and bacteriophages have found little use recently and have been used only in the very severe cases in which every measure of therapy previously found useful has been indicated.

ULCERATIVE COLITIS OF UNKNOWN ORIGIN

There still exists a fairly large group of patients who have ulcerative colitis of unknown origin. Those who still cling to the terms "nonspecific" or "idiopathic" might well apply them to these groups of cases, however, the phrase "of unknown origin" can be much more suitably applied.

Here again the ulcerative disease may be extensive, involving long stretches of small and large intestine, or it may involve only the rectum and sigmoid. Whatever segment is involved, the appearance of the lesion is at variance with those of the conditions described having a specific cause and strikingly at variance with the appearance of the bowel in the streptococcal variety of ulcerative colitis. Agglutination of *Shigella paradysenteriae* will be absent. Cultures made from the lesions and examinations of the stools will not be diagnostic. The lesions will be distributed irregularly and tend to resemble those of amebiasis or tuberculosis. Yet, usually one will detect differences. The differences are sometimes hard to describe and it has been said that the ulcers are characteristic by being so uncharacteristic. The same thing will hold true as far as the roentgenologic examination is concerned. This is the group of cases that will particularly tax the physician's ingenuity, and the response to one form of therapy or another will often be minimal.

REGIONAL ULCERATIVE COLITIS

Another form of ulcerative colitis which may or may not be of similar origin to the last described has been designated as a regional type of ulcerative colitis. The lesions involve isolated segments of intestine and may involve any segment much in the manner of regional ileitis except that here the site of the disease is the colon. The lesion may be subacute or chronic and usually is quite destructive, but also there may be evidence of hyperplastic changes. Commonly segments of the intestine from 6 to 12 inches long are found to be involved, with perfectly normal bowel distal and proximal to the lesion, and the rectum is never involved. In other words, this segmental type of colitis involves regions of the large intestine above the view of the sigmoidoscope. The wall of the involved segment is also stiff and thickened but the involvement is not as diffuse, regular and smooth as in the streptococcal type of ulcerative colitis. Thus the roentgenologic examination is the most important objective method of establishing a diagnosis.

Usually such a regional type of colitis remains localized to a segment of large intestine for months or years.

Very occasionally, however, it has been known to spread orad and caudad, so that ultimately even the distal portion of the ileum has become involved. The latter has initiated a difficult situation, indeed, and has always brought up the question whether this and so-called regional ileitis may not be the same or closely related conditions. However, the fact that regional ulcerative colitis usually remains localized to the large intestine, whereas regional ileitis commonly spreads from the ileum proximad to involve the jejunum and distad to involve the cecum and ascending colon raises a very definite question of their being separate entities.

In these cases the medical treatment is largely confined to the problem of rehabilitation for future surgical treatment. If the patient has fever and other concomitants of an active infectious disease the preoperative administration of succinylsulfathiazole in large amounts for days or weeks is indicated. If the patient has lost much weight and is anemic, these conditions should be corrected. Every known measure of therapy should be invoked to bring the patient to the best state of nutrition and reduce the infection to a minimum before resection is undertaken.

ALLERGIC COLITIS AND AN INTESTINAL DISORDER OF THE NATURE OF A DEFICIENCY SYNDROME

The type of intestinal disorder of the nature of a deficiency syndrome, other than sprue and pellagra, should actually not be discussed here. It is brought up only because there are still some who feel that the deficiency state plays a primary role in some of the types of ulcerative colitis which have been discussed. The history of patients suffering from an intestinal disorder in which a food deficiency is important is usually characteristic. Such persons may have gone for months or years on an inadequate dietary regimen. The result may be atrophy of the intestinal wall. The appearance of the bowel through the sigmoidoscope may suggest diffuse hyperemia. No real ulcers will be present. The roentgenogram may show dilatation of the large intestine with minimal changes of the mucosal pattern in the form of what appears to be a "fuzziness" of the mucous membrane, and in the small intestine a typical pattern of barium puddling and segmentation will be observed.

What has been said about the deficiency syndrome affecting the intestine might also be applied to so-called allergic colitis. Every one will accept the fact that there are patients who exhibit symptoms of intestinal allergy. Few will be impressed by the thought that such allergy is a primary factor in ulcerative intestinal disease. It seems obvious that occasionally in severe cases of intestinal allergy mucosal abrasions may occur, so that ulcers of a transient nature may be present. There is, however, little or no evidence available that these form the basis of a type of ulcerative colitis. It would seem better to consider intestinal allergy as a condition quite apart from the great problem of ulcerative enterocolitis, in the realization that it may play a part in many ulcerative intestinal inflammations but that it is not necessarily causative in any of them.

The treatment of these two conditions would seem obvious.

SUMMARY

There are many varieties of ulcerative colitis. It is of the utmost importance that the nature and cause of the disease in a given case be established as nearly as possible. Each form of colitis described has some characteristic features which set it apart from the others.

In the streptococcic variety the diffuseness of involvement and the typical proctoscopic picture together with the finding of the streptococcus are important. In the amebic variety the presence of *Endameba histolytica* is essential. In tuberculous colitis the presence of *Mycobacterium tuberculosis* together with the typical roentgenologic observations is diagnostic. In colitis due to virus of venereal lymphogranuloma the positive Frei reaction and the characteristic appearance of the lesions are essential. In colitis due to *Shigella paradysenteriae*, significant agglutination titer of the blood serum is important. In colitis associated with a deficiency state the history is all important. In so-called allergic colitis the allergic reactions of the patient will be helpful. In the groups of unknown cause and of the regional type, continued and careful study is essential. It is important that cases of the latter types be carefully distinguished from ulcerative colitis of specific cause, for in each type the treatment varies significantly and so one cannot stress too greatly the importance of a careful differential diagnosis.

INFLAMMATORY LESIONS OF THE COLON

SURGICAL ASPECT

THOMAS E. JONES, M.D.
CLEVELAND

The generally recognized inflammatory diseases of the colon are appendicitis, tuberculosis, actinomycosis, radiation stricture, lymphogranuloma, chronic ulcerative colitis and diverticulitis. Obviously it is impossible to discuss all of these in any great detail in this short time. Therefore most of the time will be utilized in discussion of the more difficult and distressing ones, namely chronic ulcerative colitis and acute and chronic diverticulitis.

Appendicitis is the most common inflammatory disease of the colon. Certainly, every one agrees that the treatment is surgical—the earlier the better. The optimum time for operation in the delayed case depends on the judgment of the individual surgeon. Yet two things are quite apparent in spite of constant teaching: 1. The diagnosis is not made early enough. 2. The mortality is still too high, chiefly because of delayed recognition. Throughout the United States the mortality is quoted as being between 4.5 and 5 per cent. There is no doubt that the use of sulfonamides has helped to reduce the mortality and especially the morbidity in this disease, but their beneficial value should not lead to any attempt to use them in the so-called early case in preference to surgery.

Owing to public health measures tuberculosis and actinomycosis of the colon are becoming rare. When they occur the cecum is the segment most commonly involved. The diagnosis is generally made by x-ray. The treatment is surgical and involves a right colectomy. The technic should be the one with which one is most adept, namely the one or two stage method with the open or closed anastomosis. I would offer one word of caution. Do not relax your judgment or surgical technic in the hope that sulfonamide will save you. In the past few months reports on the value of penicillin in the treatment of actinomycosis have been rather

encouraging. The disease is chronic and slow, and if recognized a trial with the new medication is certainly indicated before surgery is attempted. At the present time we have under treatment a woman with multiple fistulas into the pelvis, colon and vagina who in a three week period has made excellent progress as evidenced by gain in weight, decreased discharge and normal temperature. The process has been of two years' duration without relief from all other treatments.

Lymphogranuloma chiefly involves the rectum and extends into the sigmoid. The chronic inflammation involves all the coats and produces pain, discharge and stricture. Medical treatment and dilation have failed to cure the disease, and frequently we have resorted to colostomy. Often the patient will improve considerably with a colostomy, but there is still considerable incapacitation from pain and discharge. After considerable experience with this pathologic process Zininger¹ recently reported a series of cases showing that the best results come from abdominoperineal resection of the rectum in two stages with a permanent colostomy.

Radiation stricture of the rectum and sigmoid is always to be considered when a patient complains of bowel trouble following radium and x-ray therapy for carcinoma of the uterus. This may occur months or years after successful therapy and is frequently overlooked (in 1 case eight years). Its recognition is very important because, if it is mistaken for recurrence of cancer and further irradiation is advised, irreparable damage may be caused to normal organs, such as fistula into the bladder or rectum. The rate of recurrence in cancer is so high that almost any abdominal or pelvic pain may quite naturally and logically be attributed to malignant extension or metastasis. Before arriving at this conclusion, thorough sigmoidoscopic and roentgenographic studies should be made to eliminate the possibility of this curable condition.

I have encountered 18 patients with stricture in the small and large intestine, most of whom have been salvaged by recognition and appropriate surgery.

CHRONIC ULCERATIVE COLITIS

Regardless of the hope offered us for many years by the introduction of serums, vaccines, diet and sulfonamides, it cannot be said that there is any specific treatment at the present time for chronic ulcerative colitis. Much was hoped from the sulfonamide drugs, and certainly no one prayed for it more than the surgeon. With the failure of one compound another would appear for trial, almost as rapidly as the "one-a-day vitamins." My observation is that the sulfonamides have helped some, but I note that this therapy is not used alone. All other helpful things, diet and so forth, have been used in conjunction, and improvement cannot be attributed solely to specific therapy. We must not lose sight of the fact that the disease varies widely in gravity. It may appear suddenly and its severity be so great that death may occur in a period of a few weeks, or the attack may be less violent with few symptoms despite decided pathologic changes as seen by proctosigmoidoscopy.

The most striking and common clinical characteristic is the tendency to chronicity with recurrent mild to severe exacerbations. One patient may have several recurrences in one year, while another may go five years or longer with freedom from attacks. With this in mind it is readily understood why there exists a

From the Cleveland Clinic.
Read before the joint meeting of the Section on Surgery, General and Abdominal and the Section on Gastro-Enterology and Proctology at the Ninety-fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

1 Zininger, M. M. Cancer of Rectum. *Cincinnati J. Med.* 24: 25 (March) 1943.

wide difference of opinion as to the relative merits of various modes of therapy and as to the results obtained by any particular type of treatment. It baffles the surgeon as well as the medical man. How can the surgeon know that colostomy has arrested the process when that particular patient may have had immunity from attack for many years? This might also be true with any new therapeutic agent.

Pathologic Anatomy—The disease tends to involve all coats of the bowel. The mucosal surface is denuded to a greater or less extent, and healing results in scar with or without heaping up of mucosal islands, pseudopolyposis, and ultimately stricture. The muscularis becomes thickened and the serosa edematous and injected. Healing of the muscular coat results in fibrosis and narrowing of the lumen of the rectum and colon. These changes alter physiology and result in nutritional deficiency from loss of food and fluids by diarrhea. It may act as a focus of infection, occasionally causing arthritis.

Complications—(1) Perforation with general peritonitis or localized abscess with fistula formation (5 per cent), (2) hemorrhage (5 per cent), (3) stricture and narrowing of the lumen, (4) pseudopolyposis with a question of malignant degeneration (1 per cent).

Surgery has a definite place in the treatment. In early cases there is a division of opinion. There is also a division of opinion regarding the acute fulminating variety, if not complicated by hemorrhage. Surgery is definitely indicated for the chronic intractable variety. Cave and Mackie² state that when extreme anatomic changes have occurred it is vain to hope for restoration to normal.

Obviously, the only surgical treatment is ileostomy with or without colectomy. After ileostomy most patients improve generally and gain materially in weight but often are annoyed with frequent discharge of mucus and blood by rectum. In these cases it is necessary to do a colectomy. This is not an emergency operation and should be done in two or three stages after the patient is rehabilitated. Even then it has a mortality of 10 to 12 per cent. The optimum time for such a procedure is not less than three months after ileostomy. In a small group of cases (about 5 per cent) this process is limited to one segment of the colon. In such cases resection is advised, using the same technic as for malignant disease. The end results in this group of cases have been very satisfactory.

Diverticulitis—In routine examination of the colon one will find about 60 cases of diverticulosis for every thousand cases examined. Of these 60 cases about 8 cases, or approximately 15 per cent, will present complications. I know of no abdominal ailment which calls for more individualization or taxes our surgical ingenuity more than diverticulitis and its complications. For practical discussion diverticulitis may be classified into three groups: (1) diverticulitis with enterospasm, (2) diverticulitis with infiltration and (3) diverticulitis with perforation. Group 1 is the most common of the three groups and is characterized by increasing constipation, change in bowel habits and soreness in the lower part of the abdomen. Frequently an attack may be precipitated by a strong laxative taken for the constipation. There is rarely any elevation of temperature or leukocyte count. In these patients it is possible to palpate a spastic sigmoid which is definitely tender.

The x-ray examination shows a characteristic finding of diverticula with a double saw-tooth appearance of the sigmoid due to spasm of the circular muscle fibers. Treatment in this stage is medical: rest in bed, hot packs, antispasmodics and small doses of phenobarbital. If the process does not subside under this treatment, it may progress to stage 2, namely, diverticulitis with infiltration. X-ray examination shows an increase in the deformity due to inflammation and edema of the bowel wall. The filling defect is quite long. This is a valuable point in differentiating the process from carcinoma, in which the filling defect is limited to a narrower segment. Furthermore, the edema in the bowel wall may close off the ostiums of the diverticula so that they may not fill with barium and consequently are not visualized.

The treatment in stage 2 is medical also until complications arise. Obstruction is the chief complication in this stage. It is due to tremendous thickening in the mesentery and all coats of the bowel. Here clinical judgment alone determines the optimum time for surgical intervention. The duration of the ailment, the general condition of the patient, the degree of distention and the presence or absence of vomiting must all be considered in making the decision. I tend to be conservative. If surgery is indicated in this stage I think it should be limited to a colostomy at some distance above the mass, preferably the transverse colon. This procedure will take care of the emergency, and the process will usually subside. After convalescence, progress studies by sigmoidoscopic and roentgenographic examination will determine the future course. The process may subside entirely so that the colostomy may be closed, but the patient should be encouraged to keep the colostomy for six months to a year to insure complete subsidence.

If the diverticular process is shown by x-ray examination to be limited to a 4 to 6 inch segment, it is wise to consider resection of this segment while the patient has a colostomy. If the process is more extensive, resection may not be feasible, whereupon the patient must be fully informed and must assume part of the risk if he insists on closure of the colostomy. Rigid bowel management should follow closure to prevent further trouble.

In the third stage, diverticulitis with perforation, the perforation may be acute or chronic, and, while fewer cases occur in this group, they present definite difficulties in diagnosis.

In the acute fulminating variety the symptoms are so alarming that it constitutes an emergency, and frequently the diagnosis is not made until after exploration. The preoperative diagnosis is generally acute appendicitis, volvulus or perforation of a viscus. It is not surprising that the diagnosis of acute appendicitis is most commonly made because the involved segment of the sigmoid is frequently in the midline or on the right side. The only responsibility at this time is to save the life of the patient, and, as in any emergency, we must carry out only the simplest surgical procedure, namely incision and drainage. We should not attempt to close the perforated arcus with sutures, because they will not hold in the infected edematous wall of the intestine. Furthermore, it is time consuming and traumatizing and may break down protective barriers. Many of these patients die of intestinal obstruction and not of infection, therefore, while the infection may be localizing and may be dealt with later, the use of the Miller-Abbott tube postoperatively is of great value.

² Cave H. W. and Mackie T. T. Chronic Ulcerative Colitis. South. M. J. 31: 414 1938.

The judicious use of the sulfonamides intraperitoneally and systemically is valuable. If the surgeon does not see these cases until twelve to twenty-four hours have elapsed, he must use his clinical judgment as to whether operation should be performed immediately or whether he should use symptomatic treatment and wait for localization.

Chronic or, in other words, gradual progressive perforation with formation of a peridiverticular abscess confronts the surgeon with a real problem, from both a diagnostic and a therapeutic standpoint. From the standpoint of differential diagnosis we must consider malignant disease, tubo-ovarian abscess or pathologic conditions of the genitourinary tract when there is frequency of urination and pain referred to the kidney or bladder. In the presence of a diverticular abscess one of the following processes may occur:

- 1 It may perforate into the bowel with discharge of pus
- 2 It may perforate into the bladder
- 3 It may perforate into the surrounding tissue and become walled off
- 4 It may perforate through the pelvic floor and may simulate an ischiorectal abscess or fistula in ano

If it perforates into the rectum it is a fortunate and happy sequel. Treatment is symptomatic and should be directed along medical lines. If it perforates into the bladder, a vesicocolic fistula results. This is a miserable complication evidenced by irritability of the bladder and the passage of pus, feces and gas through the urethra. The first step in handling such a condition is to make a colostomy high in the sigmoid or preferably in the transverse colon to sidetrack the fecal current. This should be followed by irrigation of the colon and bladder. If the opening is very small it may close spontaneously, but in this case the colostomy should not be closed for many months, after one is assured by cystoscopy and barium x-ray examination that healing has occurred. In most cases it is necessary to dissect the colon from the bladder and to close the openings. Obviously, it is of great advantage to have a preliminary colostomy before the procedure is attempted. Finally, if the perforation is into the mesentery or surrounding tissue it becomes walled off. Generally the inflammatory process makes its way to the abdominal wall and may be incised extraperitoneally when it points. However, during this waiting process symptoms of obstruction may develop which may cause the surgeon some anxiety. In this case a cecostomy or transverse colostomy should be performed.

Whether the abscess opens spontaneously or is opened surgically, frequently a fistula will result, and the next problem is what to do about this fistula. This will depend on many factors. If the patient did not require a colostomy, I would not do anything about the fistula for a long time. I have seen fistulas close after a year of drainage. If a colostomy has been done, undoubtedly the patient wishes it closed. In this case the fistula should be injected with bismuth to outline the tract, and a barium enema should be given to estimate the extent of the bowel involved in the diverticular process. If a small segment is involved (4 to 6 inches), resection of this segment, including the fistula, should be undertaken before the colostomy is closed. It is not good surgery to dissect out the fistula alone and close the opening, because in most cases it will fail and the fistula will reform.

2020 East Ninety-Third Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs BARGEN AND JONES

DR DONOVAN C. BROWNE, New Orleans. Unquestionably to Dr. Bargen must be given credit for our much clearer pathologic and clinical concepts of certain of these entities. Whether one wishes to subscribe to his classification remains a matter of legitimate opinion and stimulates study. With the available data, avoiding the legion of unsupported hypotheses, I find myself somewhat in accord—certainly when viewed purely from the histopathologic and clinical standpoint. Some years of observation in an area where diarrheas and dysentery are not uncommon have failed to yield sufficient evidence in any manner to establish thrombo-ulcerative colitis as a stage of, or *aftermath of, bacillary dysentery*, either the acute or the chronic form. Coexisting disease entities occur all too frequently with diseases of the colon. This week we have pointed statistically to a 12 per cent incidence of concomitant disease in some 800 cases of amebiasis, which becomes significant in instances of failure to respond to adequate therapy. This may explain many of our failures. A most important feature of this presentation aside from giving an excellent summary of what we know and may well depend on in ulcerative lesions of the colon, it points vividly to what we do not know. With much improved photography, as presented by Dr. Buie, a better understanding may result. Certainly when greater numbers may see and study the same lesion the possibility of interpretations coinciding are increased, also the much more common use of the proctoscope increases the probability of biopsy and pathologic diagnosis. I have never been able to understand the fear and ultraconservatism manifest by so many in taking biopsies. Certainly it is neither difficult nor dangerous. The diagnosis as usual remains the basis for therapy. The sulfonamides in thrombo-ulcerative colitis have been disappointing in our hands and must remain an adjunct to management of the disease, but in lymphopathia I wish to stress that patients after long months of treatment have been rewarded with satisfactory results.

DR. RAYMOND W. MCNEELY, Chicago. There is no standard surgical management which is applicable in every case of chronic ulcerative colitis. Rest of the colon is important in the acute phase. Ileostomy should be done before irreparable damage to the colon has occurred. This operation is delayed too long in most instances. Patients with ileostomies should not suffer from nutritional disturbances—if they are carefully supervised and if the chemical and nutritional imbalances are corrected as soon as they appear. No one regards a colectomy as a curative procedure. It is done in order to remove a useless damaged intestine which by its presence may continue to undermine the health of the patient. It is a source of danger from hemorrhage, stricture, perforation and malignancy. Colectomy should not be done as a heroic procedure when the patient's condition is considered desperate but should be reserved for the chronic cases and then done in stages. One of my keenest disappointments has been the failure of either the sulfonamides or penicillin to have any appreciable effect on this group of patients. Some patients with diverticulitis have few symptoms before perforation takes place. Those who develop a perforation with spreading peritonitis require immediate exploration. A proximal colostomy or ileostomy with exteriorization of the lesion will meet the requirements in most cases. There are some patients in whom a perforation permits a rapid flow of large bowel contents into the free peritoneal cavity. In the absence of restraining adhesions the contents diffuse quickly and cause a widespread fulminating peritonitis which usually destroys the patient. In chronic infiltrative and obstructive types of diverticulitis great care should be exercised in preparing these patients for surgery. I have found sulfonamide drugs very helpful in reducing the morbidity and mortality in these cases. Conservatism should be the rule. Probably a definite transverse colostomy with a spur, not a colostomy in continuity is the treatment of choice. Many of the infiltrative varieties will clear up if set at rest for a long time. Those which do not improve may be prepared adequately with succinylsulfathiazole and then resected. In localizing abscesses there is a tendency to do too much surgery. Simple incision and drainage is the wisest procedure.

DR M H STREICHER, Chicago I agree with Dr Barga about the importance of the classification, so that one is talking about the proper type of case. In the last year and a half, at the University of Illinois, we have worked on sulfathalidine. We have reported bacteriologic, clinical and chemical blood studies in 47 cases. Our results with sulfathalidine have been encouraging. Dr Barga's statistics on the average of good results in ulcerative colitis compare well with ours over an eighteen or nineteen year period. That leaves about 15 per cent which do not get along or which meet with some complications that need surgery. I hope Dr McNealy is right, that a new miracle will cut that 15 per cent down to zero.

DR J ARNOLD BARGEN Rochester, Minn. The indications for surgery for the various types of ulcerative colitis in my experience vary with the type of colitis at hand. For the streptococcal type of ulcerative colitis the only curative surgery would seem to be an ileostomy proximal to the inflammatory intestinal disease followed by subtotal or total colectomy. In the ulcerative colitis of undetermined etiology, not including the segmental variety, this too would be the surgical treatment of choice. This, then, brings up the question of when to advise surgery. From a study of a series of 185 consecutive ileostomies reviewed by Drs Pemberton, Ashburn, Lindahl and myself, a review of which was published in the *Annals of Internal Medicine* in January 1943, and from our experience in observing these patients, it has become apparent that ileostomy and other subsequent surgery is best limited to complication of ulcerative colitis such as extensive perirectal infection with abscess and fistula, intestinal stricture, extensive secondary polyposis, a walled off colonic perforation, secondary malignant neoplasia and the occasional case of severe arthritis. Then, of course, ileostomy is not performed for ulcerative colitis but rather for another condition complicating the ulcerative colitis. Only occasionally will ileostomy be indicated for the so called intractable case of ulcerative colitis. Hardly ever will it be indicated for the severe fulminating case of ulcerative colitis which we have referred to repeatedly and which was also mentioned by Dr Jones. Surgical results with the latter type of case have been most disappointing. The use of one of the sulfonamides, the anticolitis serum, blood transfusions, intravenous feedings, administration of concentrated oxygen and other supportive measures have carried many of these cases through to recovery. Surgery for the regional type of ulcerative colitis or the case of segmental tuberculous colitis is usually in the nature of resection of the diseased segment and establishment of ileocolostomy in some form. Surgery for the ulcerative colitis due to the virus of lymphopathia venereum will rarely require more than a colostomy. For other types of ulcerative colitis, particularly the streptococcal type, colostomy in our hands has been disappointing. Great progress in the management of the various types of ulcerative colitis has been made, not the least important of which is our knowledge of a satisfactory classification of the various forms of ulcerative colitis. The group of diseases which we have referred to here still stands as a challenge to the clinician and medical investigator as well.

DR THOMAS E JONES Cleveland I agree entirely with Dr McNealy's remarks about anastomosis. Most cases of peritonitis result from leakage at the suture line and not from contamination at the time of operation. Therefore this may happen with the closed or open type of anastomosis. That is why I emphasized that one should do the type of operation with which one is most familiar.

Intelligence Tests—The inference that laborers are dull as a rule is mistaken. Data from Army intelligence tests show for example that at least one fourth of those who reported their occupations as laborers in the sample population study did better than the median of the total Army population. Tests made in factories showed that scores of workers in certain labor groups varied all the way from 60 to 169 and while the median score was 112 (slightly lower than for any other group in the factory) it was significant that there were among the laboratory group and draftsmen, and also among the foremen those whose scores were below the median.—Davis, John E. *Principles and Practice of Rehabilitation*, New York: A. S. Barnes & Co., Inc., 1943.

USE OF PENICILLIN IN PREVENTION OF POSTOPERATIVE EMPYEMA FOLLOWING LUNG RESECTION

REPORT OF A CONTROLLED STUDY

Most attempts to measure the potentialities of a drug in wound infections, whether in terms of prophylaxis or of treatment, suffer from extreme degrees of variation in the lesions studied. The wound variations occur in respect to size, depth, anatomic location, inflicting agents, degrees of contamination, types and numbers of organisms present and the amount of contained foreign matter. Wounds also vary with the individual patient as to age, concomitant disease, nutrition, individual host resistance and healing capacity. Still another source of variation is the management of the wound, the time elapsed between injury and definitive treatment, the extent of debridement and of wound closure, the degree of tension in closed wounds, adequacy of immobilization, frequency of dressings and the duration of hospitalization. In established infection all of these variables are present plus the factors of bacterial invasion, bacterial toxins and bacterial symbiosis, which further complicate the picture. Hence it is considerably more difficult to assess the efficacy of a drug in surgical infections than in the more uniform nonsurgical diseases such as pneumonia, cerebrospinal meningitis or gonorrhea, in which factors relating to the presence of a wound are nonexistent.

In any clinical study it is important to avoid erroneous conclusions based on impression by employing adequate and comparable controls. When the clinical material is variable, controls are difficult to evaluate, however, if similar cases in experimental and control groups are paired, the influence of variation will be reduced. If this method is followed it is essential that the experimental and control cases be observed concurrently.

This study was designed to minimize the factors of variation, to offer adequate and comparable controls and to provide a clearly definable end point as the basis for evaluating the agent. Therefore our objective could be simply stated as follows: "To determine if penicillin is of value in the prevention of empyema following transection of the bronchi."

Several minor considerations have necessarily entered into the project, such as the therapeutic response to penicillin manifested by the underlying disease and the

This work was carried out under a contract recommended by the Committee on Medical Research between the Office of Scientific Research and Development, Washington, D. C. and the University of Pennsylvania. The Responsible Investigator on this contract was John S. Lockwood, M.D. This study was made possible by the cooperation of the surgical, bronchoscopic, bacteriologic and x-ray departments of the Temple University Medical School and Hospital, the Hahnemann Medical College and Hospital and the Abington Memorial Hospital. Technical assistance was given by Miss Cecile Chemerda, Mrs. Catherine Collins, Dietz, Miss Jean I. McKinney and Miss Jean Gates.

effect of systemically administered penicillin on the bacterial flora of sputum and bronchial secretions. This study also presented an opportunity to determine whether bacteria in the bronchi are the source of infection in those cases in which empyema developed and to evaluate the use of penicillin in the treatment of extrapulmonary suppurative infections following lobectomy or pneumonectomy.

In a study of the prevention of infection following elective lung resection, the clinical material is standardized in a rather unique way. With removal of lung tissue a dead space remains, which fills rather promptly with serum and with varying amounts of blood. The only avascular tissue present is that distal to the ligated hilar structures, and this is minimal in amount and more or less constant in extent. There is very little mobile soft tissue to aid in the walling off of infection, and the effectiveness of host resistance alone is quite limited. These conditions offer an ideal situation to permit bacterial growth, namely a collection of enriched body fluid in a rigid dead space containing no omental-like structure to aid in localizing the infection. Thus any organism that becomes established in this fluid will tend to produce an empyema even though it may not be primarily of a highly invasive type. At the same time the pleura provides a partial barrier against extending infection.

It appears that these circumstances offer an excellent opportunity for evaluating the usefulness of penicillin as a prophylactic agent.

OUTLINE OF THE PROJECT

1 Patients were considered for this study only after the decision had been made to perform either lobectomy or pneumonectomy. This avoided the influence of penicillin prophylaxis in selecting patients for operation.

2 Cases were paired as closely as possible to minimize the influence of uncontrollable variation, 1 case being assigned to the control series and its mate being placed in the group for treatment.

3 The decision as to whether a patient was to receive penicillin or serve as a control did not rest with the operator but with an impartial observer.

4 Penicillin was given in experimental cases for one week preoperatively and two weeks postoperatively.

5 In experimental cases 150,000 units of penicillin was administered daily with the exception of one 8 year old child, who received 100,000 units daily.

6 The intramuscular route of administration was used in all cases, injections being given every two hours in equal amounts.

7 No local penicillin was used in the pleural space before, during or after operation unless an obvious empyema had developed, in which case the experimental result was already determined.

8 In the event that empyema developed in control cases, penicillin therapy was given by various routes in an effort to control the infection.

9 No sulfonamides or other therapeutic agents were used either systemically or locally in treated or control cases.

10 Three thoracic surgeons participated in this study. Two of them worked together employing identical techniques which facilitated the pairing of cases. The third surgeon worked independently and provided pairs which were kept separate from those of the other two surgeons.

11 One stage procedures were performed in all cases included in the final analysis.

12 A daily record was kept of the amount, character and odor of all sputum.

13 Every patient was examined carefully for the presence or absence of active tuberculosis.

14 Cultures of sputum or bronchial secretions were usually obtained for two days before penicillin was started in treated cases or for two days before operation in control cases. Frequent cultures were made of the sputum of patients in the penicillin series during the week of preoperative therapy. Postoperatively sputum cultures were obtained at frequent intervals for at least two weeks.

15 In one of the collaborating hospitals, bronchoscopic examinations were performed frequently, specimens being obtained for culture.

16 Complete x-ray studies were obtained in all cases.

17 Chest fluid for definitive bacteriologic analysis was usually obtained by needle aspirations, although frequent cultures were made of tube drainage.

18 A comprehensive work-up, including routine and special laboratory studies as indicated, was done in all cases.

The following is an outline of the operative routine of the collaborating surgeons. Two of the men working in one clinic followed procedure A and the other surgeon used procedure B.

Procedure A—I Pneumonectomy. Incision was made in the third interspace through the pectoralis muscles and extending from the sternum to the anterior axillary line, with continuation of the incision in the interspace to the paravertebral line. Ribs were spread and not resected. The mediastinal pleura was opened and the pulmonary artery and veins were dissected free. Each was doubly ligated and transfixed with number 1 chromic catgut and divided between transfexion and distal ligatures. Remaining tissue was dissected from the bronchus, which was doubly clamped with heavy hemostats. The field was isolated with acriflavine gauze and the bronchus amputated at the distal clamp, leaving the stump protruding from the proximal clamp. The stump was then swabbed dry and culture made of this material. The stump was treated with phenol and alcohol and closed with Michel clips. Isolating gauze and all instruments and gloves were discarded, after which the reflected pleura or pleural flaps were closed over the stump with continuous and interrupted 00 chromic catgut. The chest was closed in layers, and air was aspirated to give a mild negative pressure.

II Lobectomy. The differences were only in the approach, which was made through the seventh rib bed. After resection, drainage was instituted through a stab wound by mushroom or straight catheter.

Procedure B—I Pneumonectomy. A curved parascapular or posterolateral incision was made and carried through all the muscles in the line of the skin wound. The sixth rib was usually removed. The mediastinal pleura was incised and the main bronchus to the lung was located. This was clamped with a noncrushing clamp close to the bronchial margin. A crushing clamp was then applied distally to this point and the bronchus divided between them. The pulmonary artery to that lung was doubly ligated with one silk ligature and one transfexion suture ligature, it was then divided distally. The pulmonary veins were treated in a similar manner and the lung dissected free and removed. The bronchus was closed with a medium silk ligature or simple end sutures of fine silk. A flap of parietal pleura was mobilized and sutured to the anterior bronchial surface.

with interrupted fine silk sutures. The chest was closed in layers and pressure controlled by aspiration of air. In 8 of the 13 cases done by this method tube drainage by intercostal catheter was utilized.

II Lobectomy. The technic is much the same as for pneumonectomy. Closed drainage with an intercostal number 24 French catheter was used in all but 5 cases. The drainage tube was connected to a water sealed bottle.

Criteria.—We have chiefly concerned ourselves with the value of penicillin in preventing the development of empyema. Because of this patients who died within four weeks postoperatively from causes entirely unrelated to infection are not considered among the completed cases. Cases that came to operation but were not resectable and those with recent empyema or draining sinuses were likewise excluded from the statistical analysis.

In this study patients with purulent pleural fluid containing viable organisms and demonstrating a systemic reaction characteristic of infection were considered to have empyema. All purulent chest fluids have been studied bacteriologically, and all have produced bacterial growth at one time or another. The mere presence of bacteria without evidence of pus or other signs of infection was not considered to be indicative of infection. A febrile response of some degree is to be expected following lung resection and may often be explained on a basis other than infection. First the operative procedures are exceedingly traumatizing and prolonged and result in a dead space which contains blood and serum, the absorption of which is usually associated with fever. Secondly, there is a disturbance of physiologic equilibrium. Third, patients with suppurative pulmonary infections or tuberculosis usually have some involvement in the remaining lung tissue, and activation of these lesions frequently follows lobectomy or pneumonectomy. When the fever is due to infection the patients appear toxic, the elevation of temperature is usually sustained and the diagnosis is completed with recovery of purulent material and viable organisms from the chest.

Chest fluid for definitive studies was obtained by thoracentesis unless tube drainage from the pleural space revealed copious amounts of pus.

If at the end of four weeks after operation there was no evidence of infection a patient was considered uninfected in this study. The only pyogenic infection which this limit excludes is 1 purulent empyema which developed after seven weeks in a control case. Two patients in the tuberculosis series who received prophylactic penicillin developed tuberculous empyemas after the four week period of evaluation. One of these showed a nonpathogenic staphylococcus after the bronchus had opened.

RESULTS

A total of 48 patients had partial, single or multiple lobectomy or pneumonectomy. Of these, 41 are suitable for analysis by the criteria set forth. Seven patients died within four days postoperatively without infection. Six patients who were explored without removal of lung tissue were excluded from the study, since bronchi were not transected.

Pairing of cases has been difficult to achieve. Consequently, only 30 of the 41 have been suitably paired. However, the presence of unpaired cases does not significantly alter the results, since the differences between treated and control groups is so great.

Of the 41 patients 21 received penicillin prophylactically and 20 served as controls. None of the penicillin patients showed evidence of a pyogenic empyema, while 12, or 60 per cent, of the controls developed pleural suppuration. One patient with bronchogenic carcinoma who received penicillin did become infected but is excluded from the statistical analysis, since he died on the fourth postoperative day from causes not related to infection. This case is discussed under postoperative deaths where the reasons for exclusion are explained.

BRONCHIECTASIS AND MULTIPLE ABSCESSES

Penicillin demonstrated its greatest value in cases of suppurative pulmonary infections. Twenty-one patients had partial or total lung resection for bronchiectasis or multiple lung abscesses. Seventeen of them had partial single or multiple lobectomies, while only 4 of them had total lung resections. The treated group included 10 lobectomies and 2 pneumonectomies. None of these patients developed any evidence of intrapleural infection. The control group consisted of 7 lobectomies and 2 pneumonectomies, in all of which empyema developed. In 3 of these cases, 2 lobectomies and 1 pneumonectomy, death occurred. Infection was overwhelming in all 3 instances and contributed to ultimate death of the patients.

Surgery was an elective procedure in all 21 of these cases. Preoperatively there was little febrile reaction and the volume of sputum was minimal.

Of the 21 cases, 18 have been appropriately paired. The incidence of empyema remains the same, 100 per cent in control cases and none in treated cases.

Four patients had gross contamination of the pleural space at operation resulting from an unavoidable spill of purulent material. Three of these cases, 2 lobectomies and 1 pneumonectomy, were in the control group. The fourth case, a partial lobectomy included in the penicillin series, showed no evidence of empyema. From this case and 2 of the controls, hemolytic streptococci were recovered preoperatively in the sputum. The same organism was present in the empyema which subsequently developed in the control cases and was present in a large abscess found in the surgical specimen removed at operation from the patient who received penicillin.

The patients who received penicillin for seven days preoperatively were in good condition when the therapy was instituted, therefore there was little evidence of clinical improvement that could be attributed to penicillin. Five of the 12 patients in this series demonstrated a decrease in sputum volume before operation and 2 of them exhibited a change in sputum character recorded as thinning and decrease in purulence. There was little evidence of penicillin effect bronchoscopically other than an occasional decrease in purulence of the bronchial secretions.

The control cases varied considerably in their postoperative course from a slight reaction to infection to a stormy course which resulted in the death of 3 patients (13, 14 and 21). The 12 patients who received penicillin had an essentially uneventful convalescence. The average daily low and high temperatures of the two groups of cases were calculated and plotted, as shown in the accompanying chart. The highest postoperative temperature recorded for a treated patient was 102.4 F., while 4 of the controls exceeded 103 F. Of the 3 patients who died of infection, patients 13 and 21 died on the

fourth postoperative day and patient 14 on the twenty-second postoperative day

The bronchial closure in all of the treated patients apparently remained secure, while 3 of the control subjects developed bronchial fistulas. There were no wound infections in the treated group, while 4 were observed among the control cases. The average number of postoperative days of tube drainage in those in whom drainage was done was 6 in the penicillin group and 38.7 in the controls who survived. The average postoperative day out of bed was 8.4 in treated patients and 24 in the controls. This includes only survivors. The average postoperative day of discharge with prophylactic therapy was 17.4, while the survivors of the nontreated group averaged 37.5 days of postoperative hospitalization. In 6 pairs of patients, all of whom survived, the treated ones remained in the hospital for a total of one hundred and twenty-three days postoperatively, while the controls totaled two hundred and twenty-five. This was a saving of one hundred and two days of hospitalization, or an average of seventeen days per patient. Secondary thoracotomy for empyema drainage was necessary in 6 of the control cases. The results are presented in the accompanying chart.

There were 4 patients in the prophylaxis group who demonstrated some degree of contralateral involvement preoperatively. None of these showed any evidence of acute activation of remaining areas of suppuration postoperatively.

TUBERCULOSIS

Fifteen patients had partial or total lung resection for tuberculosis. Seven of these were treated and 8 served as controls. Three of the operations in the treated series were lobectomies and 4 were pneumonectomies. The control group consisted of 4 lobectomies and 4 pneumonectomies. These patients were usually selected for lobectomy or pneumonectomy because of endobronchial tuberculosis with resultant stenosis or cavitory pulmonary tuberculosis which had not been amenable to collapse therapy such as pneumothorax, thoracoplasty or revised thoracoplasty. While these patients demonstrated varying degrees of superimposed pyogenic infection, their lesions were fundamentally tuberculous. Eleven of these patients were febrile preoperatively, their temperatures exceeding 100 F and some reaching 103.6 F. Two controls and 2 treated patients were essentially afebrile preoperatively.

At least 3 of the cases in this series could not be classified as elective, since it was felt that the nature of the disease required early surgical intervention.

All 15 patients were operated on by the same surgeon.

There were 5 treated and 5 control cases which could be suitably paired. The 5 paired controls showed essentially the same incidence of empyema (40 per cent) as the entire control group of 8 patients (37.5 per cent), including the 5 paired and 3 unpaired. Two of the paired prophylaxis patients (22 and 23) developed tuberculous empyema and bronchopleural fistulas after the four week period of postoperative observation. Both were heavily inoculated with tubercle bacilli by the

accidental rupture of tuberculous cavities at the time of operation. Patient 22 was discharged on the twenty-fifth postoperative day but was readmitted six days later with an empyema and a bronchopleural fistula. A biopsy of the pleura revealed tubercle bacilli, while the thin and somewhat purulent chest fluid contained non-pathogenic staphylococci. In spite of thoracotomy and an upper stage thoracoplasty, this man developed a contralateral tuberculous spread and died. Patient 23 displayed acid fast bacilli on smear of his chest fluid shortly after operation. On discharge on the forty-eighth postoperative day this patient returned to the sanatorium. Shortly thereafter a tuberculous empyema drained spontaneously through the healed wound. It was then determined that he had a bronchopleural fistula. No pyogenic bacteria were recovered from the chest fluid, cultures of which were taken on six occasions. The draining sinus is healing slowly.

Of the 7 patients in the treated series, 2 with a predominance of pyogenic infection improved clinically during the week of preoperative administration. Two others with extensive tuberculous involvement had a steady increase in temperature. Two of the 7 had a

Calculated average daily high and low temperatures in bronchiectasis and multiple lung abscesses: solid line penicillin prophylaxis series 12 cases; dotted line control series 9 cases.

slight decrease in sputum volume. The character of the sputum was not significantly altered in any of the 7.

Two of the 3 pyogenic empyemas (31 and 34) which occurred in the control group were caused by non-pathogenic staphylococci. Both cleared quickly with local and systemic penicillin therapy. The third case (35) demonstrated an untypable pneumococcus, first in the sputum, later in the empyema and subsequently in the pericardium and wound. A bronchopleural fistula developed on the thirty-second postoperative day. Death occurred two weeks later as a result of the extensive infection. Autopsy revealed a pyogenic and tuberculous empyema and pericarditis. One other patient, number 36 in this series, developed a staphylococcal empyema which was not discovered until the fifty-fourth postoperative day. Since it had been more than four weeks postoperatively when the empyema was noted, this patient is considered as an uninfected control.

Bronchopleural fistulas occurred in the 2 penicillin patients who developed tuberculous empyemas, as discussed. Fistulas also occurred in patients 31 and 35, both of whom were infected controls. There were no wound infections in the treated group, while the wounds of 2 of the controls became infected. The average number of postoperative days of drainage given patients who had tube drainage and survived was 4.0 in the treated series and 3.3 in the nontreated. One of the 2

treated patients with a tuberculous empyema required a late thoracostomy, the other pointed, ruptured and drained spontaneously. Three of the controls required early thoracostomy. The average postoperative day out of bed in the treated series was 11.1 and for the controls 16.9. The average postoperative day of discharge was 27.0 for the penicillin group and 35.4 for controls. There were two deaths due to infection, one in the

A tabulation of the results in this series of cases is presented in table 2.

TUMORS

None of the patients with bronchiogenic carcinoma, whether treated or control, developed infectious complications. One patient in this group had a partial lobectomy after tumor biopsy examined by frozen section and reported nonmalignant. However, on examination of

* Spontaneous rupture ** Tuberculous

treated series and one in the control series. Both had mixed tuberculous and pyogenic empyemas. Of the fifteen experimental and control subjects, 11 had a sustained postoperative fever. Nine cases exceeded 103 F, 3 of which reached 105 F. The temperature of 2 patients fluctuated between 101 and 103 F. Four patients, 3 of whom received penicillin, did not exceed 101 F. Four controls and 1 treated patient had definite activation and spread of their tuberculous lesions following lung resection.

The resected lung tissue a malignant tumor was found. This group of patients includes only 5 cases, 2 treated and 3 controls. Only one pairing can be made. The average days of drainage, postoperative day out of bed and postoperative day of discharge are not significantly different in the penicillin and control series. These results are presented in table 3. Because of the limited number of cases and the absence of infection it is impossible to draw any conclusions as to the effects of penicillin.

EMPYEMA CASES

Control patients who developed empyema were treated with penicillin. Treatment varied in these patients as to the dosage and route of administration. Patients 17 and 31 received only local therapy. Both had sterile fluid soon after treatment was instituted. In case 17 the clinical response was prompt. Both patients later developed bronchopleural fistulas. The local doses given were 20,000 units and 25,000 units respectively at frequent instillations. The empyema in case 31 was produced by *Staphylococcus albus* while the other infection was due to a nonhemolytic streptococcus.

Three patients were given only systemic therapy, 2 of whom 13 and 35, received a continuous intravenous infusion of 100,000 units daily. Both had pneumococcal empyema and died in spite of penicillin therapy. Patient 35 was later shown to have a tuberculous empyema. The third patient, number 16, was also given 100,000 units daily, but by intramuscular injection. The infecting organisms were hemolytic streptococci and coagulase negative staphylococci. Response to treatment was prompt.

Seven of the infected control patients received both systemic and local therapy. Five of the 7 received

Hemophilus influenzae, nonhemolytic *Staphylococcus aureus* and *Bacillus pyocyaneus*. After penicillin had been given a thorough trial it was stopped. A type XXII pneumococcus then made its appearance in the drainage and remained present until the time of discharge. The empyema in this case first became evident with a severe wound infection. The infection in the chest was localized and necessitated surgical drainage. The patient was discharged on his forty-eighth postoperative day, only to be readmitted seventeen days later because of chronic cough and continued drainage.

Patients 14 and 21 died in spite of local and systemic therapy. Both had hemolytic streptococci as well as other organisms in the chest fluid.

No additional penicillin therapy was given to the 2 treated patients who developed late tuberculous empyemas. Both received the full twenty-one day course of prophylactic therapy.

In the presence of a bronchopleural-cutaneous fistula the value of penicillin in the treatment of empyema was reduced. This was due to constant recontamination and the inability to prevent the drug from leaking out of the infected space through the open bronchus or drainage tract. The bronchus of 1 of the infected con-

100,000 units daily systemically while the other 2 received 67,000 units and 50,000 units respectively. Local therapy in these 7 cases varied from 8,000 to 50,000 units daily, the smaller dose being used in case 19. Of the remaining 6, 3 received, locally, approximately 25,000 units per day, 1 received 40,000 units daily and 2 received 50,000 units daily.

Two patients (20 and 24) who received local and systemic therapy had a prompt response. Patient 20 was infected with anaerobic hemolytic streptococci. He was discharged after his empyema had responded to therapy, only to be readmitted a month later with a recrudescence of his infection which necessitated thoracotomy. The empyema in case 34 was produced by nonpathogenic staphylococci. Recovery was rapid.

Three infected patients, 15, 18 and 19, seemed to improve slightly with the use of combined systemic and local treatment. This response was purely clinical in 15 and 18 consisting of a decrease in toxicity. All 3 are still draining at 56, 101 and 102 postoperative days respectively. Patient 19 developed a bronchopleural fistula. He was originally infected with hemolytic streptococci but this organism disappeared soon after penicillin therapy was instituted. Although still draining, the patient has been discharged. Patient 15 is infected with microaerophilic nonhemolytic streptococci which have been repeatedly recovered from his drainage. The empyema in case 18 contained a mixed flora including

control patients opened after complete wound healing had taken place, with a resultant pocket of infection about the bronchus. Local penicillin was given by bronchoscopic instillation through the open bronchus into the infected cavity with considerable success.

Of the 4 patients who died subsequent to pyogenic empyema patient 21 developed a massive streptococcal mediastinitis and patient 13 succumbed following an overwhelming pneumococcal empyema. Patient 35 died as a result of tuberculous and pneumococcal empyema, mediastinitis, pericarditis and wound infection. Patient 14 died suddenly following uncontrollable hemorrhage into the wound, which had become grossly infected.

DEATHS OF NONINFECTED PATIENTS

Seven patients died postoperatively after lung resection without evidence of infection. Six of these had removal of an entire lung and 1 a right upper lobe lobectomy. The single lobectomy was performed on a white man aged 49 with multiple abscesses of the right upper lobe. He was considered as a control and did not receive penicillin at any time. His postoperative course was uneventful for three days. On the third day after eating his dinner he died very suddenly. No autopsy was obtained.

Of the 6 patients who died following pneumonectomy, 1 was a white woman aged 28 with extensive caseating tuberculosis of the right lung accompanied by bronchial stenosis. This patient received penicillin before and

after operation. Following pneumonectomy x-ray showed a wide contralateral spread. Her course was progressively downhill until she died in great respiratory difficulty on the sixth postoperative day.

The 5 remaining patients had resection because of bronchogenic carcinoma. All 5 were included in the penicillin prophylaxis series. Death occurred in all instances within four days postoperatively. Autopsy was performed on 3 of these patients. Postmortem examination was not permitted on the other 2, 1 of whom developed a left sided hemiplegia about twelve hours before death. The consensus was that he had a cerebral embolus. The other patient, on whom autopsy was not performed, died approximately eight hours after pneumonectomy. He suddenly became very pale, gasped a few times for breath and died. During this episode his blood pressure could not be obtained. It is believed that the patient died from hemorrhage into the chest.

Among the 3 patients on whom autopsy was performed 1 was a man aged 61 who developed a hacking, nonproductive, continuous cough soon after operation. He was quite exhausted at the end of seventy-two hours and died as a result of acute myocardial failure. Autopsy revealed pulmonary congestion and emphysema of the remaining lung. It is of interest that an acute fibrinous pericarditis was found at autopsy, culture of which was sterile. Another patient, a white man aged 22 died following pneumonectomy. Autopsy revealed no metastasis of the bronchogenic carcinoma but acute passive congestion and pneumonitis of the remaining lung. There was evidence of pronounced cardiac dilatation and cardiac insufficiency. Because of a severe anemia the patient received 3,000 cc of whole blood during the preoperative and operative period. This may have predisposed to the development of pulmonary edema.

The last of these patients was referred to previously, since he received penicillin and showed evidence of infection. This patient was a white man aged 53 who had a rather complicated course. The surgeon in this case elected to perform a two stage procedure. At the first operation he determined the resectability of the lung and ligated the bronchus. Two weeks later pneumonectomy was performed. The patient was given penicillin for seven days before the second stage procedure. At the time of resection it was discovered that the bronchus had perforated at the site of the ligature with a resultant collection of pus lying about it. This pus produced the same pneumococcus, type III, which had been present in the sputum for several weeks. Immediately after pneumonectomy the patient had a relatively uneventful course except for evidence of positive pressure at one time. On the second postoperative day, while drinking milk, he choked, became unconscious and died rather suddenly in respiratory distress. Postmortem examination revealed a positive pressure pneumothorax on the left side but no demonstrable leak in the bronchus stump. The stomach, trachea and bronchus contained milk. The right lower lobe was atelectatic, the middle lobe was partially atelectatic. The upper lobe was emphysematous and showed congestion. There was no evidence of neoplastic metastasis or infection. This case is excluded from the analysis of results for the following reasons. Since the first stage of this procedure was done without benefit of the drug and the second was done under penicillin prophylaxis, it is difficult to classify this patient as experimental or control. It is impossible to determine whether the perforation and

subsequent infection took place during the week following bronchial ligation when penicillin was not given or during the week of therapy prior to pneumonectomy. If the perforation and infection took place before the drug was given it is unlikely, in view of our experience in the treatment of postoperative empyema, that the systemic administration of penicillin would eliminate the type III pneumococcus from this localized infection in the presence of an open bronchus. Sputum cultures, which revealed this organism on nine occasions from 14 specimens obtained prior to therapy, showed the disappearance of the pneumococcus from the sputum after three days of penicillin administration. This is in keeping with the absence of evidence of infection at autopsy, which suggests that penicillin was effective in controlling the infection after the bronchus was closed and the lung was removed. There is nothing to suggest, either from the clinical course or from the autopsy findings, that the infection played any significant part in the patient's demise.

It is remarkable that among 22 pneumonectomies there were eight deaths, three of which were due to infection and five showed no evidence of infection. The 5 noninfected patients had been included in a group of 6, all of whom had bronchogenic carcinoma. All 5 had received penicillin before and after operation. Three patients with carcinoma serving as control pneumonectomies had no infectious complications and all survived. These figures seem to indicate that the use of penicillin may predispose to postoperative death following lung resection for pulmonary cancer. However, the lack of conformity of autopsy reports and clinical findings prior to death seems to make this most unlikely. The distribution of the fatalities is probably fortuitous.

BACTERIOLOGIC STUDIES

Unfortunately facilities did not permit a complete bacteriologic survey in every instance, however, many of the patients were studied sufficiently to permit some interesting observations and conclusions.

Initially it was our plan to evaluate the effect of penicillin on aerobic and anaerobic sputum flora since this presented a simple procedure with readily accessible material. We also contemplated following the number of organisms per cubic centimeter of sputum. This, however, was soon abandoned, since the figures varied so widely and followed no definite trends.

Later it appeared that cultures of bronchial secretions obtained by bronchoscopic aspiration were of greater value than sputum cultures, since this excluded many of the common mouth organisms. Frequent bronchoscopic specimens were therefore obtained to supplement the sputum studies in one institution. Still later in the study, bronchus biopsy or bronchus swab cultures were obtained from the pathologic specimens as soon as they were removed from the chest. These were usually dropped directly into culture mediums.

Frequent cultures were made of chest fluid. This was especially interesting in the infected control cases in which penicillin was given.

RESULTS

Sputum exhibited a highly diversified flora, usually containing mouth organisms such as alpha streptococci, gram negative diplococci, pneumococci and diphtheroids. The penicillin given in experimental cases for seven days before operation exhibited only one consistent bacteriologic effect. Hemolytic streptococci disappeared from the sputum soon after therapy was instituted in

6 cases. Pneumococci and staphylococci were usually unaffected by the systemically administered penicillin, although in an occasional case these organisms disappeared from the sputum. Gram negative bacilli occurred frequently and often persisted throughout the period of hospitalization. *Hemophilus influenzae* was most conspicuous among these.

Bronchus biopsy cultures were obtained in 14 cases. Six of these showed no growth and included specimens not placed directly into culture mediums.

In 9 of the patients who developed empyema we had recovered preoperatively, from either sputum or bronchial secretions, thirteen of the causative or saprophytic organisms. Of the thirteen organisms thus traced between the sputum or bronchoscopic specimens and empyema fluid, seven made an intermediary appearance in bronchus stump cultures. The thirteen organisms thus traced included aerobic and anaerobic hemolytic and nonhemolytic streptococci, pneumococci, nonpathogenic staphylococci, *Hemophilus influenzae* and *Bacteroides*.

Chest fluid for culture was obtained both from tube drainage and by needle aspiration. Cultures obtained from drainage tubes were not considered reliable enough to contribute to the diagnosis of empyema unless there were copious amounts of purulent material, obviously draining from the pleural space. However, tube cultures afforded a ready means of following empyema flora. The appearance of contaminants such as proteus and pyocyaneus was common in these cultures. Many of the specimens obtained by tube drainage were sterile, especially those obtained soon after operation. Fluid aspirated by thoracentesis produced viable organisms in several instances in which the fluid was not purulent and did not become so. We did not consider these patients infected merely on the basis of the presence of organisms, whether in treated or in nontreated patients. We were often able to demonstrate that these organisms were the same as those obtained previously from sputum, bronchial secretions or stump biopsy cultures.

Patients who developed empyema, according to the criteria set forth, were given penicillin therapy. As discussed previously, dosage and route of administration of the drug varied. Response to therapy was by no means constant from either clinical or bacteriologic points of view. From the 12 patients with pyogenic empyema 28 organisms were obtained by culture of chest fluid. These organisms were distributed as follows: 8 streptococci, 5 of which were hemolytic, 6 strains of staphylococci, only 1 of which was hemolytic and pathogenic (determined by coagulase test), 4 pneumococci, 1 tubercle bacillus, 2 *Bacteroides*, and 7 gram negative bacilli. Of the gram positive organisms, anaerobic streptococci and pneumococci appeared most resistant to the penicillin therapy. Patients without fistulas demonstrating an empyema produced by staphylococci or aerobic hemolytic streptococci appeared to respond most promptly. Patients who developed fistulas demonstrated a great variety of organisms in their chest fluid.

It was noted that in several instances certain organisms disappeared from the sputum postoperatively in control cases.

PENICILLIN CONCENTRATIONS

The postoperative chest fluid of 4 patients has been tested for the presence of penicillin with negative results, except in 1 instance in which blood was obtained on aspiration. This specimen clotted on standing and showed a concentration similar to that found in blood.

The patients whose fluid was assayed were receiving only intramuscular therapy. The absence of the drug in chest fluid makes it difficult to understand the mechanism of the protection obtained from systemically administered penicillin. This is especially true in 1 case in which there was an obvious spill into the pleural space at operation of approximately 1 ounce (30 cc) of pus which contained hemolytic streptococci. The bronchial secretions of 2 patients were tested for the presence of penicillin. No drug was detectable in either.

Blood samples taken on 4 patients receiving 150,000 units of penicillin daily revealed concentrations varying from 0.030 unit per cubic centimeter to 0.36 unit per cubic centimeter, depending on the method of analysis and the time at which the specimen was obtained in relation to the cycle of injection, absorption and excretion. Apparently the administration of 12,500 units of penicillin every two hours maintains a detectable penicillin concentration in the blood serum.

COMMENT

Originally it was our plan to gather 50 treated cases and 50 control cases, feeling that this number would be required in order to establish the value of penicillin in preventing postoperative infectious complications after lobectomy and pneumonectomy. However, 41 experimental and control cases so clearly demonstrate the effect of penicillin that we do not feel that it is justifiable to continue the use of controls. The frequency of hemolytic streptococcus empyema in control cases probably accounts for much of the success obtained with the use of sulfonamides in recent years.

The fact that we have been able to pain 30 of the 41 patients satisfactorily plus the fact that the results in paired cases are not significantly different from those of the aggregates substantiates the validity of the conclusions drawn from this study. Most of the patients were in uniformly good condition when subjected to surgery, which eliminated certain other variable factors.

The occurrence of postoperative empyema in all control lobectomy and pneumonectomy, bronchiectatic and lung abscess cases is very striking when compared with the absence of postoperative infection in those receiving penicillin. Among the 20 control cases the incidence of empyema was 100 per cent in suppurative pulmonary infections, 37.5 per cent in pulmonary tuberculosis and zero in the bronchiogenic carcinoma group. It thus appears that penicillin prophylaxis will have its greatest usefulness in those cases in which there is pyogenic pulmonary suppuration.

In comparing noninfected treated patients and noninfected controls, no appreciable differences are noted as to the number of days of tube drainage, the postoperative day out of bed and the postoperative day of discharge. This demonstrates the limitation of the usefulness of penicillin to the prevention of infectious complications following lung resection for suppurative lesions of the lung. There was no evidence that penicillin was of value beyond this limitation.

It is our opinion that the preoperative administration of penicillin has been a most important feature of this study. The drug given during this period probably serves to control acute and chronic infection in the pulmonary tissues, which reduces the possibilities of postoperative infections. In addition, the preoperative use of penicillin affords maximum therapeutic effect at the time the pleural space is exposed to bronchial contamination. We also feel that it is essential to administer an effective therapeutic dose of penicillin given at fre-

quent intervals by a route of administration which offers technical simplicity and adequate absorption

The routine use of local penicillin therapy applied directly into the pleural space after lung resection admittedly offers attractive theoretical possibilities. In this study we have avoided this method of prophylactic administration since it would constitute another variable factor and make it impossible to separate the effects of systemic and local therapy. It appears that systemic therapy is adequate, however, local therapy may offer an additional mechanism of protection.

SUMMARY

1 Penicillin administered for one week preoperatively and two weeks postoperatively in doses of 150,000 units daily given by intramuscular injection appears to be useful in preventing postoperative pyogenic infections following lobectomy or pneumonectomy.

2 Patients with bronchiectasis or multiple lung abscesses who received prophylactic penicillin and were subjected to partial or total lung resection showed no evidence of postoperative infection, had less fever, had fewer days of tube drainage, were allowed out of bed earlier and were discharged sooner than control patients, all of whom became infected.

3 Penicillin is apparently of no value in preventing or controlling tuberculous infections.

4 Penicillin administered systemically and locally was of variable value in treating postoperative suppurative infections which developed in control cases.

5 No toxic reactions have been noted in 41 patients who received a full course of penicillin therapy.

6 In patients who developed empyema the etiologic organism was often recovered from the sputum and bronchial secretions before operation and from bronchus stump cultures taken at the time of resection.¹

PENICILLIN X

SUCCESSFUL TREATMENT OF GONORRHEA WITH A SINGLE INTRAMUSCULAR INJECTION

HENRY WELCH, PH D

LAWRENCE E. PUTNAM, M D

WILLIAM A. RANDALL, PH D

AND

ROBERT P. HERWICK, M D, PH D

WASHINGTON, D C

In a recent issue of *Science*¹ it was reported that gonorrhea had been successfully treated with single injections of 100,000 units of commercial penicillin incorporated in a beeswax-peanut oil base. For the past several months we have had an opportunity to investigate the properties of so-called penicillin X,² sometimes referred to as factor X, or allopencillin. This material was furnished to us by three manufacturers.³ A small amount of crystalline penicillin X⁴ was also made available to us.

1 Since this report was submitted for publication 5 additional pneumonectomies have been performed in accordance with the procedure outlined in this study. All 5 patients received the prophylactic course of penicillin. Four of them were resected for bronchiogenic carcinoma and 1 for a bronchial adenoma. None of these patients became infected and all of them survived.

3 Commercial penicillin and penicillin X in this article refer to the sodium salts of these substances.

4 Obtained through the courtesy of the Upjohn Company, Cutter Laboratories and Cheplin Biological Laboratories.

5 Robert D. Coghill of the Northern Regional Research Laboratory supplied the crystalline penicillin X.

When assayed by the cup-plate method⁵ the potency of crystalline penicillin X is approximately 900 units per milligram, while crystalline penicillin⁶ has a potency of 1,650 units per milligram. In addition, *in vitro* studies (serial dilution) show that penicillin X is more effective than commercial penicillin against a strain of *Klebsiella pneumoniae* type A and a strain of *Bacillus cereus*. No difference in effect could be shown between penicillin X and commercial penicillin on four strains of *Staphylococcus aureus*. However, preliminary studies indicate that penicillin X is three to five times more effective in protecting mice against 10,000 lethal doses of pneumococcus type I than commercial penicillin.

On the basis of the increased activity of this new preparation against certain organisms in comparison with commercial penicillin, it appeared desirable to determine the effect of penicillin X on the gonococcus. Accordingly, 68 patients with gonorrhea,⁷ most of whom were sulfonamide resistant, were treated with a single intramuscular injection of 25,000 units of penicillin X. The group consisted of 35 males and 33 females. Our criterion of cure was three negative cultures obtained one, three and five days after treatment had been completed, although in some cases, because of menses or other factors, cultures were taken at greater intervals and over a longer period of time. Sixty-four patients, or approximately 94 per cent of those treated, were cured. For comparative purposes a group of 58 patients with gonorrhea (31 males and 27 females) were treated with a single intramuscular injection of 25,000 units of commercial penicillin. Using the same criterion, 37 patients, or approximately 64 per cent of those treated, were cured. It is of interest that 3 of the patients in whom we failed to obtain a cure with commercial penicillin were cured by a subsequent treatment with a single injection of 25,000 units of penicillin X.

Studies of the blood concentration were made on 7 patients treated with penicillin X and on 8 patients treated with commercial penicillin. These concentrations were determined with the serial dilution technique using *Bacillus subtilis* as the test organism, one-half hour, one hour and two hours following intramuscular injection. During the first two hours after treatment a consistently higher concentration of penicillin X was maintained in the blood. Urinary excretion studies were made over a period of eight hours on 9 patients, 4 treated with penicillin X and 5 with commercial penicillin. During the first two hour period 59 per cent of the penicillin X injected was excreted, as compared with 68 per cent of the commercial penicillin. After eight hours the total excretion of penicillin X was 71 per cent as compared with 80 per cent of commercial penicillin. Further studies are in progress using larger doses of penicillin X in a single intramuscular injection to determine its efficacy and rate of excretion at higher levels.

Although the number of cases reported here is small, if further work substantiates the fact that a large proportion of cases of gonorrhea can be cured with a single intramuscular injection of penicillin X, the public health control of this disease, which has been materially affected by the use of commercial penicillin, will be further facilitated.

Clinical Notes, Suggestions and New Instruments

AN UNUSUAL CASE OF CUTANEOUS HODGKIN'S DISEASE WITH TERMINAL BLOOD STREAM SPREAD

S. R. BERSACK, M.D.
Radiologist, Mount Alto Veterans Hospital
WASHINGTON, D. C.

The patient who is the subject of this report was encountered in a study of 225 cases of Hodgkin's disease.¹ The unusual features of the case and the rarity of cutaneous Hodgkin's disease are deemed sufficient justification for the publication of this report.

History—W. K., a white man aged 44, a World War I veteran, was admitted to the Edward Hines hospital on Nov. 4, 1940. His father died at 78 of "old age." His mother died of pneumonia at an age unknown. Two sisters died in infancy and 1 sister died at 21 of pneumonia. Two brothers, his wife and 2 children are alive and well. There was no history of diabetes, tuberculosis or carcinoma in the family. His occupation was that of an auto repairman and lately he held a job as a road tester. He had an appendectomy in 1918. There

was no history of venereal diseases. He smoked ten cigarettes a day and consumed 1 pint of whisky a week.

In March 1939 he first noted a lump on the midposterior aspect of the right calf. For a period of six months this lump gradually grew until it attained the size of a hen's egg. At this point the skin ulcerated and for several weeks there was drainage of a purulent exudate. Soon afterward several more lumps appeared under the skin of the surrounding region as well as on the opposite

nodes were slightly enlarged and firm. The chest and abdomen were negative to percussion and auscultation. The blood pressure registered 106/72. The skin of the left buttock presented multiple shallow ulcers which were more or less confluent, covering an area 10 cm in diameter. The skin of the entire right popliteal space was similarly ulcerated. Many brown and grayish black spots were present on both legs.

Fig. 2—Microscopic appearance of section of older skin lesion. The typical Sternberg cells are evident in the corium.

The blood count showed hemoglobin 60 per cent, red blood cells 3,200,000 and white blood cells 9,200, with 79 per cent polymorphonuclears and 21 per cent lymphocytes. Blood Kahn and Wassermann reactions were negative. Urinalysis was negative. Blood culture was sterile on four examinations. Blood smear was negative for malarial parasites. The Widal test was negative. The agglutination test for undulant fever was negative. A roentgenogram of the chest was negative except for elevation of the right dome of the diaphragm.

Course—Three days after admission the patient developed several new skin lesions on his right flank. These at first manifested themselves as 0.5 cm erythematous areas. The same day they grew to become slightly raised nodules in the skin. The following day one of these pinkish nodules was excised for biopsy. Microscopically it showed normal epidermis with a minimal reaction about several small blood vessels (fig. 1). The reaction consisted of slight endothelial and fibroblastic proliferation. A moderate number of lymphocytes were seen scattered in the corium. It is interesting to note that this skin nodule showed nothing more striking than some scattered lymphocytes, even though it was clinically a well developed erythematous nodule. The microscopic appearance of the specimen from the older and larger skin lesion was typical of Hodgkin's disease (fig. 2).

On the eighth hospital day the patient developed a sudden spread of the skin nodule. Literally hundreds of small circumscribed papular nodular erythematous lesions appeared in the skin from head to foot (figs. 4, 5 and 6). This was associated with severe chills and stupor. The temperature rose and stayed at 103-104 F. On the last day it reached 105.5 F. The patient died on Nov. 20, 1940, sixteen days after admission.

Fig. 1—Microscopic appearance of section of one day old erythematous skin nodule from right abdominal wall showing nothing more striking than some lymphocytes in the corium. Also a minimal endothelial and fibroblastic reaction about several blood vessels can be seen.

calf. These new lesions also became ulcerated. On Aug. 26, 1939 the patient presented himself to a private clinic, where a diagnosis of idiopathic multiple hemorrhagic sarcoma was made. This diagnosis was thought to have been confirmed by a skin biopsy. The biopsy slide was requested for review purposes but could not be obtained. While under the care of the private clinic the patient received irradiation to the skin lesions all of which responded readily except for the one ulcer in the right popliteal space. This area received a total of 4,023 roentgens.

Early in September 1940 the patient began to experience severe chills approximately every six hours. These were followed by periods of profuse sweating and exhaustion. They were associated with a loss of appetite.

Examination—On admission to this hospital the patient appeared well developed and well nourished but acutely ill. The temperature was 101 F, pulse rate 120 and respiratory rate 38. The skin was dry and had a suggestion of a yellow tinge. The pharynx was slightly injected. The gums were tender, with evidence of recent extraction of teeth. The submaxillary lymph

Fig. 3—Microscopic appearance of section of a Hodgkin's nodule obtained at autopsy. This shows a moderate amount of fibrosis, many fibroblasts, only a moderate number of lymphocytes and many multinucleated hyperchromatic giant cells of the Sternberg type.

Am. J. Clin. Path. 13: 253-259 (May) 1943.

Autopsy—The body was 170 cm in length and weighed 160 pounds (73 Kg). The skin of the face and neck presented innumerable small (2 to 4 mm in diameter) pink, slightly raised nodules. They could be felt throughout the scalp. Many nodules were also found in the skin of the back. A small number were present on the chest and abdomen and a few on the thighs.

The skin of the arms presented a moderate number of flat grayish white round scars 5 mm in diameter. No nodules were observed on the forearms, hands and feet. The dura had a few flat nodules. None could be found in the brain substance. Beneath the mucosa of the trachea, larynx, the laryngeal surface of the epiglottis, the esophagus and the stomach were many small pinkish nodules 2 to 3 mm in diameter. The mucosa was not ulcerated. The nodules were fairly uniformly scattered, increasing in number as one proceeded downward.

Many minute nodules were also found in the parietal pleura,

a small number in the lungs, an occasional nodule in the parietal peritoneum and several in the pericardium, spleen and both testes as well as two minute gray spots on the cortical surface

in the capsule of the pancreas. The abdominal nodes measured 1 to 3 cm, the pelvic nodes up to 5 cm. Microscopically these nodules showed a moderate amount of fibrosis, many fibroblasts, a moderate number of lymphocytes and many multinucleated hyperchromatic giant cells of the Sternberg type (fig. 3).

The autopsy diagnosis was Hodgkin's disease of the skin with metastases to the abdominal and pelvic lymph nodes, trachea, lungs, pleura, esophagus, stomach, liver, spleen and lumbar vertebrae.

COMMENT

The case of cutaneous Hodgkin's disease here reported illustrates a terminal spread through the blood stream. The fact that no malignant cell could be found in the microscopic examination of the early skin nodules caused by blood stream spread is in favor of a virus etiology of Hodgkin's disease. The hematogenous dissemination must have been mediated through the

Fig. 4—Appearance of face in a case of cutaneous Hodgkin's disease with terminal blood stream spread.

Fig. 6—Literally hundreds of small circumscribed papular and nodular erythematous lesions covered the skin from head to foot.

Fig. 5—Trunk of patient

of the kidneys. The liver was studded with numerous small nodules. The mediastinal lymph nodes were small, soft and black. A moderate number of enlarged lymph nodes were found in the retroperitoneal region along the iliac vessels and

humoral content of the blood. The only alternative would be to incriminate the few lymphocytes found in the initial stage of a new focus. They might possibly be the vectors of the noxus. The theory of a virus etiology of Hodgkin's disease is an attractive one in that it will explain the early clinical features of an inflammatory nature and also the later development into a seemingly autonomous neoplastic disease. The virus theory deserves further clinical and experimental study. It may be worth while to attempt transmission experiments with blood derived from a patient who, as in the present instance, is exhibiting blood stream spread.

SUMMARY

A patient with cutaneous Hodgkin's disease with rapid terminal blood stream spread presented the additional unusual feature of ulceration of Hodgkin's skin lesions.

The occurrence of terminal blood stream spread without any evidence of embolic cellular element dissemination is consistent with a virus etiology of Hodgkin's disease.

THE EFFECT OF STARVATION ON DIABETES
INSIPIDUS

JOHN P. PETERS, M.D., NEW HAVEN, CONN.

It has recently been demonstrated by Winter Sattler and Ingram¹ that the polyuria of experimental diabetes insipidus in animals is greatly reduced or eliminated by starvation. The following case illustrates the same phenomenon in a woman with diabetes insipidus complicated by vomiting of pregnancy.

M. H., a woman born Jan. 1, 1918, was admitted to the New Haven Hospital March 15, 1944 for pernicious vomiting of pregnancy. Her last menstrual period had been Dec. 31, 1943. She was reported to have been seriously ill with "acidosis" when 3 to 4 years old but knew no details of the illness. At 16 she was treated with injections for amenorrhea. At 18 she suffered for a full summer with intermittent attacks of headache and vomiting. She was, however, able to return to college in the fall and complete her course. Regular, spontaneous menstruation did not begin until she was 21 years old. She was married in February 1943. In addition to this she stated that as long as she could remember she had always imbibed enormous amounts of water, up to 7 or 8 quarts a day, but, because of a large bladder capacity, had never suffered undue inconvenience from urinary frequency.

She was small, well developed and moderately nourished, quite dehydrated, and weighed less than 90 pounds (41 Kg.). Her temperature was 100 F. by mouth, pulse rate 70, blood pressure 108/64. There was a slight exophoria of the right eye associated with a refractive error. The optic disk outlines were slightly blurred, especially along the nasal margins. The knee jerks were extremely hyperactive. Except for this and the signs of pregnancy physical examination was essentially normal. Blood count revealed 3 million red blood cells, 11 Gm. hemoglobin, and normal leukocytes and differential count. The Kahn test was negative. In spite of her dehydration the initial urine specimen had a specific gravity of only 1.004, otherwise it was negative. On March 21 the blood nonprotein nitrogen was 19 mg. per hundred cubic centimeters, serum carbon dioxide 23.0 milliequivalents per liter, chlorides 102.2, serum protein 5.89 per cent, albumin 3.98, globulin 1.91. X-ray films of the skull revealed no abnormalities.

Through March 17 she was permitted nothing by mouth, receiving moderate amounts of isotonic solution of sodium chloride and 5 per cent glucose by infusion. The vomiting ceased and the urine volume was moderate. On the 18th she vomited when attempts at feeding were resumed. For this reason food and fluids were again stopped and she was given on the 19th an infusion of 2,500 cc. of isotonic sodium chloride and glucose solution. On this day, when she received in addition to the infusion only 270 cc. of fluid by mouth, she voided 5,750 cc. of urine, 3,500 cc. during the four hours that the infusion was running. On the 20th and 21st, when she took and retained small amounts of food, the urine volume was 3,550 and 3,200 cc. respectively, with obvious fluid intakes of 2,000 and 2,750 cc. In spite of extreme restriction of salt, as vomiting remained in abeyance and the food intake increased, the urine volume rose steadily to reach 5,550 cc. on March 28 with an obvious fluid intake of 4,350 cc. Attempts to control the diuresis with injections of pitressin or nasal insufflation of posterior pituitary powder were thwarted by abdominal cramps and vomiting which these medications induced. Moreover, as her diet increased her fluid intake rose out of proportion. This forced her to drink more than her stomach could tolerate and provoked a recurrence of vomiting on a profuse scale.

The pregnancy was terminated operatively on March 3. On this day and the next when she received no food, the urine volume again fell to 2,000 cc. per day with intakes of 3,500 and 2,400 respectively. As diet was resumed it rose steadily to reach the magnificent figure of 8,550 cc. with an obvious fluid intake of 6,650 cc. By means of intranasal posterior pituitary

powder, which she was now able to tolerate, it proved possible to reduce the urine volume below 4,000 cc. per day, which relieved her of all inconvenience.

When she was last seen on Sept. 26, 1944 she was subjectively in excellent health weighing 110 pounds (50 Kg.). By using the pituitary powder two or three times a day she was able to avoid all inconvenience from the polyuria. Both thirst and frequency recurred, however, as soon as she discontinued the therapy. The urine specific gravity was 1.005.

This appears to be an authentic case of diabetes insipidus in which the polyuria was suppressed by starvation, in this instance occasioned by vomiting of pregnancy. The reaction to infusion also illustrated dramatically the diuretic influence of salt in this condition.

AGRANULOCYTOSIS TREATED WITH PENICILLIN

LIEUTENANT COLONEL LESLIE B. SMITH, MAJOR FRANK COHEN,
AND CAPTAIN RALPH G. NICHOLS
MEDICAL CORPS, ARMY OF THE UNITED STATES

Spontaneous leukocytic regeneration has been reported¹ to occur in cases of agranulocytosis when the primary or secondary infections were controlled by specific chemotherapy (sulfonamide).

We believe that the reporting of 2 cases of agranulocytosis successfully treated with penicillin is timely. To date 1 such case has been cited,² however, there have been none reported in detail.³

REPORT OF CASES

CASE 1—A Negro aged 18 years was admitted to the Station Hospital, Camp Wolters, Texas, Feb. 28, 1944 complaining of sore throat, fever, cough and pain in his chest.

The history revealed that he had had measles and mumps as a child and "malaria" eighteen months before admission without recurrence. Although he denied having had a penile lesion or other manifestations of syphilis, the syphilitic register revealed that the Kline test had twice been positive in November 1943, that the Kahn and Wassermann tests were positive in January 1944 and that the spinal fluid was normal. The diagnosis was late latent syphilis, for which he had been given seven doses of 0.06 Gm. of mapharsen and four doses of 0.2 Gm. of bismuth subsalicylate during the four weeks preceding this admission. He had had a sore throat and fever for a day following the fourth and fifth doses of mapharsen. These symptoms recurred one day after the seventh dose of mapharsen and became so severe that he was admitted to the hospital three days later.

At the time of admission he was acutely ill. The temperature was 100.4 F., the pulse rate was 98 per minute and the respiratory rate was 22 per minute. The tonsils, oral pharynx and nasal membranes were hyperemic and edematous. The anterior and posterior cervical lymph glands were slightly enlarged and tender, and there were a few coarse rales in the bases of both lungs. The remainder of the physical findings were normal. He was given symptomatic treatment, acetylsalicylic acid and saline gargles during the first twenty-four hours of observation.

The second day he appeared to be critically ill. His temperature had gradually increased to 104 F. and the leukocyte count was 5,390 per cubic millimeter. The first differential blood count, done during the morning of the second day, revealed 0 per cent neutrophils, 95 per cent lymphocytes, 3 per cent monocytes and 2 per cent eosinophils. A second blood study made seven hours after the first, revealed 4,000 leukocytes per cubic millimeter with 1 per cent stab forms and again 0 per cent segmented neutrophilic polymorphonuclear cells. The erythrocyte count was 4,200,000 and the hemoglobin was 80 per cent. Heterophile agglutins were not present in the blood.

1 Winter, C. A., Sattler, D. G. and Ingram, W. R. The Relationship Between Salt Intake and the Polyuria of Experimental Diabetes Insipidus. *Am. J. Physiol.* 131, 363 (Dec.) 1940.

Three blood cultures were subsequently reported as showing no growth. A roentgenogram of his chest was essentially normal. A diagnosis of agranulocytosis was made.

On the third day a small shallow ulcer, containing a necrotic exudate, was present on the surface of the right tonsil. Bacteriologic studies of specimens obtained from the ulcer showed mixed organisms and hemolytic streptococci. A differential blood count showed only 15 per cent stab forms and 0.5 per cent segmented neutrophilic polymorphonuclear cells.

Penicillin therapy was begun at 4 p. m. the third day in doses of 20,000 Oxford units, intramuscularly, every three hours. Sixteen hours after the first dose the temperature was normal, general improvement was definite and the ulcer in the right tonsil was clean and much smaller. At this time the leukocyte count was 4,500 per cubic millimeter and the differential count was 37 per cent neutrophilic polymorphonuclear cells, 5 per cent eosinophils, 3 per cent monocytes and 55 per cent lymphocytes. The neutrophilic polymorphonuclear cells were divided as follows: 19 per cent segmented, 10 per cent stabs, 7 per cent juveniles and 1 per cent myelocytes.

Although the patient was definitely clinically improved and a differential blood count revealed 50 per cent neutrophils, the therapy was augmented on the fourth day by pentose nucleotide (40 cc daily) and yellow bone marrow (twelve granules each day).

Convalescence continued to be uneventful. The dosage of penicillin, the leukocytic response and the temperatures are given in chart 1. Continued observations for four weeks revealed that he remained well, that the blood count was normal and that heterophile agglutins were not present in the blood.

This patient was given three small blood transfusions, pentose nucleotide and bone marrow, however, the dramatic improvement was concurrent with the administration of the penicillin and preceded the pentose nucleotide therapy.

CASE 2—A Negro aged 31, well nourished, was admitted to the Station Hospital, Camp Wolters, Texas, March 13, 1944 complaining of sore throat and painful swollen gums.

He gave a history of having had measles as a child, typhoid at the age of 20 and some treatment for syphilis ten years previously. The syphilitic register revealed that the Kahn and Wassermann reaction were positive in January and February, 1944, that the spinal fluid was normal and that he had been given six 0.06 Gm doses of mapharsen and three 0.2 Gm doses of bismuth subsalicylate in the three week period preceding

Chart 1—Course in case 1

this illness. He stated "Each arm shot made me quite sick in my stomach." He had a sudden onset of severe "sore throat" on March 9, the day following the seventh dose of mapharsen. His gums became sore, for which he was first seen in the Dental Clinic, March 13. A stained specimen from the lesions of the gums revealed numerous fusiform bacilli and the spirochete *Borrelia vincenti*. A diagnosis was made of moderately severe, acute ulcerative stomatitis due to Vincent's organisms for which he was admitted to the hospital.

At the time of admission he was acutely ill, his temperature was 102.2 F and the pulse rate was 110 per minute, his throat was hyperemic and there were moderate ulcerations of the gums about the lower left molars. These ulcers contained a necrotic exudate. Symptomatic treatment consisting of sodium perborate gargles and acetylsalicylic acid was given. The following morning the temperature was 103.2 F. The ulcerations were more extensive and he was critically ill. The leuko-

Chart 2—Course in case 2

cyte count was 5,370 per cubic millimeter, with 0 per cent neutrophilic polymorphonuclear cells, 74 per cent monocytes, 10 per cent large lymphocytes and 16 per cent small lymphocytes. The hemoglobin was 75 per cent and there were 4,280,000 erythrocytes per cubic millimeter.

The third day the patient was very listless and apathetic. He could not take food or fluid by mouth. His temperature was 103.4 F and the pulse rate was 112 per minute. The leukocyte count was 5,600 per cubic millimeter, with only 3 per cent granulocytes. Cultures of the mouth lesions revealed nonhemolytic staphylococci.

A diagnosis of agranulocytic angina was made, and penicillin therapy was begun in doses of 10,000 units intramuscularly every three hours. His temperature remained between 103 and 104 F for twenty-four hours and then began to fall by lysis and was normal in thirty-eight hours. He was decidedly improved. The ulcers in the mouth healed rapidly and were absent by the sixth day of therapy. Granulocytes began to reappear in the blood on the second day of the penicillin therapy and continued to increase, as is shown in chart 2.

On March 22 the leukocyte count was 5,200 per cubic millimeter with 60 per cent polymorphonuclear neutrophils, 18 per cent large lymphocytes, 5 per cent small lymphocytes, 15 per cent monocytes and 2 per cent eosinophils.

In addition to the 380,000 Oxford units of penicillin, this patient was given thirty capsules of yellow bone marrow and two transfusions of 250 cc of citrated blood.

Convalescence was rapid and uneventful and he was discharged to duty thirteen days after his admission. Observations made during the next three weeks revealed that he remained well, blood counts were normal and heterophile agglutins were not present in the blood.

CONCLUSION

It is our opinion that the primary suppression of the bone marrow in these 2 cases was due to mapharsen, and that further suppression may have been caused by the secondary infection. The control of the secondary infection by penicillin therapy allowed spontaneous leukocytic regeneration to occur.

Although both of our patients received additional therapy the striking improvements were observed to occur during the first twenty-four hours of the penicillin therapy. From the results obtained in these 2 cases we believe that further trial of penicillin in the treatment of agranulocytosis is indicated.

COMPRESSION FRACTURE RESULTING FROM ACCIDENTAL
STIMULATION OF CAROTID SINUS

MAJOR CHARLES U. HAUSER
Chief of Orthopedic Section AAF Regional Station Hospital
Langley Field Virginia
MEDICAL CORPS ARMY OF THE UNITED STATES

An unfortunate complication resulting from a simple office procedure recently occurred in the orthopedic clinic of the AAF Regional Station Hospital Langley Field, Virginia. The cause of the mishap provides interesting speculation and again indicates the seriousness of even the most casual routine office procedures. For these reasons a summary of the case history is presented.

Lieut Col J B S reported to the orthopedic clinic because of intense pain and swelling of his right wrist present for three days following a flexion strain incurred during a volley ball game. Examination of the wrist revealed tenderness and swelling of the sheath of the extensor carpi radialis with crepitation on wrist flexion, increased local heat and intense pain on any motion. A diagnosis of traumatic tenosynovitis was made and plaster immobilization of the hand and forearm in a position of comfort was advised. No preliminary medication, injection or manipulation was performed. While sitting on an office stool, the patient was instructed to hold his hand in a comfortable position for the application of a light plaster cast over several layers of sheet wadding. During the application of the cast the patient complained of faintness, and his head slumped forward against his moderately tight neck band. Before the nurse could revive him with aromatic spirit of ammonia or loosen his collar band a strong convulsion gripped him, causing his back to flex sharply with all his flexors tightening in a tetanic spasm, which lasted for a few seconds. The convulsion was not unlike that which is induced in metrazol or insulin shock therapy. Unfortunately, neither the blood pressure nor the pulse was recorded during the excitement of the convulsion. He was immediately lifted from the stool and laid on the examining table, where he remained limp and unconscious for about five minutes. There was no loss of sphincter control. On recovery the patient immediately complained of terrific pains in the dorsolumbar spine, and subsequent x-ray films revealed compression fractures of the eleventh and twelfth dorsal vertebrae, resulting in about 25 per cent reduction in the width of the anterior portion of the bodies. The fractures were treated in the conventional manner, satisfactory reduction being obtained by the method of Davis, with the application of a hyperextension cast. The cast controlled his symptoms and he was able to resume his administrative duties within two months, his back supported by the body cast. The innocent appearing tenosynovitis disappeared after two weeks of plaster immobilization followed by a course of physical therapy.

In the absence of a history of similar attacks, it must be assumed that several factors contributed to the convulsion. The right carotid sinus was found to be hyperirritable, as subsequent pressure over the sinus produced dizziness and faintness. His normal fasting glucose level was 93 mg, although there was a normal response to the Evan and Rose sugar tolerance test. Since the accident occurred around 11 a m after the patient had foregone his breakfast, it was felt that his blood sugar at that time was abnormally low. Fatigue from several sleepless nights, apprehension over the original injury, pain in his wrist and the usual hospital aroma, added to the low glucose level, all helped to lower the threshold for stimulation of his normally hypersensitive carotid sinus. The pressure of a tight collar against his neck, which was acutely flexed by the weight of his unsupported head, had served as a trigger which precipitated his convulsion. Convulsions from pressure applied to a hyperirritable carotid sinus are rare but have been observed. To anticipate all these complicating factors before the application of a simple forearm cast would, of course have been impossible. The unpredictable could easily have been prevented, however if one simple precaution had been observed in the handling of the patient. This complication should help to emphasize again the danger inherent in any treatment given to a patient who is not in a horizontal position.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M D, Secretary

CHORIONIC GONADOTROPIN (See New and Non-official Remedies, 1944, p 445)

The following dosage forms have been accepted

SHARP & DOHME, INC., PHILADELPHIA

'Lyovac' Chorionic Gonadotropin, 500 International Units 5 cc A powdered preparation which, when diluted with the accompanying 5 cc of sterile distilled water containing 0.35 per cent of phenol provides a solution having a potency of 100 international units per cubic centimeter

'Lyovac' Chorionic Gonadotropin, 1,000 International Units 10 cc A powdered preparation which when diluted with the accompanying 10 cc of sterile distilled water containing 0.35 per cent of phenol, provides a solution having a potency of 100 international units per cubic centimeter

'Lyovac' Chorionic Gonadotropin, 2,500 International Units 5 cc A powdered preparation which when diluted with the accompanying 5 cc of sterile distilled water containing 0.35 per cent of phenol provides a solution having a potency of 500 international units per cubic centimeter

THIAMINE HYDROCHLORIDE (See New and Non-official Remedies 1944 p 608)

The following dosage forms have been accepted

MERCK & CO, INC., RAHWAY, N J

Thiamine Hydrochloride (Powder)

HORTON & CONVERSE, LOS ANGELES

Tablets Thiamine Hydrochloride 5 mg and 10 mg

GEORGE A BREON AND CO, INC., KANSAS CITY, MO

Tablets Thiamine Hydrochloride 10 mg

OUABAIN (See New and Nonofficial Remedies, 1944, p 314)

The following dosage forms have been accepted

CARROLL DUNHAM SMITH PHARMACAL CO, ORANGE, N J

Ampuls Ouabain Injection 0.5 cc and 2 cc

Ampuls Ouabain and Digitalis Tablets 2 cc Packages containing two 2 cc 0.5 mg ampuls of ouabain and one vial of 20 tablets digitalis 0.1 Gm

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies 1944, p 373)

The following dosage forms have been accepted

WILLIAM R WARNER & CO, INC., NEW YORK

Ampuls Solution Aminophylline 0.24 Gm in 10 cc

Tablets Aminophylline 0.1 Gm

TETANUS ANTITOXIN (See New and Nonofficial Remedies, 1944, p 544)

The following additional dosage form has been accepted

PITMAN-MOORE CO, INDIANAPOLIS

Tetanus Antitoxin Pepsin Digestion Refined Vials containing 1,500 units

ASCORBIC ACID (See New and Nonofficial Remedies, 1944, p 620)

The following dosage form has been accepted

CARROLL DUNHAM SMITH PHARMACAL CO, ORANGE, N J

Tablets Ascorbic Acid 100 mg

RIBOFLAVIN (See New and Nonofficial Remedies, 1944, p 613)

The following dosage form has been accepted

ENDO PRODUCTS, INC., RICHMOND HILL, N Y

Tablets Riboflavin 5 mg

PYRIDOXINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p 618)

The following dosage form has been accepted

MERCK & CO, INC., RAHWAY, N J

Vitamin B₆ Hydrochloride (Powder)

SATURDAY DECEMBER 16, 1944

STUDIES ON PINTO'S DISEASE

The discovery in Cuba in 1938 of the spirochetel etiology of Pinto's disease gave a new impetus to the study of the disease itself and also to that of yaws and syphilis. Within the last five years numerous reports have appeared concerning the occurrence of pinta in several countries in the American continent in which the condition had not been previously observed. With the publications of Fonso Gandolfo and his co-workers¹ in Argentina and the article of Lieberthal² in this country it would seem that the disease is prevalent in practically the whole American hemisphere. True only 3 patients have been studied by Lieberthal in Chicago but, since 2 of them came from southern states near the heavily infected Mexico it is highly probable that more cases will be diagnosed in the future. Although comprehensive reviews have already been published in English,³ one must read the numerous original publications in Spanish to realize fully the painstaking efforts required for the solution of each of the problems posed by the disease in a long sequence of events that started hundreds of years ago.

The conquistadores, including Cortez himself, apparently observed Pinto's disease and wrote about it. Polanco in 1760 included pinta in his *Diccionario Berecochea* and Corona in 1811 speak for the first time of the beneficial effects of mercury, and fifty years later J. J. Leon⁴ gave the first clinical description of the disease, a study considered today as a classic. The effectiveness of arsphenamine was established in 1913 by Gratz in Bogota. Almost simultaneously but independently Menk in Colombia and Gonzalez Herrejon in Mexico found in 1925 that the Wassermann reaction was positive in a high percentage of cases and the

following year Gonzalez Herrejon⁴ promulgated his thesis that pinta was a spirochetel disease different from yaws and syphilis. This conception was brilliantly confirmed in 1938 by a Cuban group, Alfonso Armenteros, Grau Triana, B. Saenz, Pardo-Castello and Leon y Blanco, and by the subsequent studies of Leon y Blanco in Mexico. The mycosic theory currently accepted and sponsored by authorities such as Sabouraud was eliminated forever.

One also finds in the Spanish publications some refreshing anecdotes supplying the inside and humane part of the story. There was naive Father Alzate, who in 1759 thought that the disease was introduced in Michoacan as the result of a volcanic eruption, or the fantastic tales about men contracting pinta through sexual intercourse with some species of giant lizards, also the more realistic Bishop Fuero, who concretely blamed a woman from Chiapas for the spread of pinta—not a venereal disease though—throughout his diocese. We wonder about the power of deduction of J. J. Leon,⁵ who in 1862 ascribed the disease to the ingestion of corn infected by a definite species of fungus, adding, however, that there was in the lesions a virus capable of transmitting the disease to other human beings through a vector insect. We enjoy reading about the innate wisdom of the Mexican Indians who got jobs in the mercury plants whenever affected by pinta and how this empirical observation suggested to Soberon y Parra⁶ the use of arsphenamine and bismuth compounds for treating the disease.

Credit for the study of the early manifestations of pinta goes entirely to Leon y Blanco, who inoculated himself with infectious material and followed both clinically and bacteriologically the evolution of his lesion. Thus two important Latin American contributions to medicine, namely the final proof of the spirochetel etiology of pinta and that of the unity of Oroya fever and verruga peruana by Carrion in 1885 were the result of experiments on the experimenter himself. As it is well known, Carrion died the victim of his own scientific curiosity.

However, historical research by Aguirre Pequeño⁷ has disclosed an observation by Iturbide in 1870 concerning a soldier who wounded himself with his bayonet after stabbing a person affected with pinta and contracted the disease himself. More important, though, are the studies that Tellez⁸ described in his monograph. He stated that on numerous occasions he transmitted the disease to healthy persons by scarification with a lancet soiled with blood of pinta's patients, and he thought that insects of the genus *Empis* were vectors of the disease through the same way of transmission.

6 Aguirre Pequeño F. *Medicina* 22: 13 1942.

7 Tellez G. *El mal de Pinto* pamphlet Mexico 1889.

Tellez also stated that pinta was an exanthematic form of syphilis

Contrasting with the wealth of information on the human disease naturally or experimentally induced, nothing as yet has been seriously done in attempting to reproduce the disease in animals. This situation should not last long, for one can easily visualize how fruitful it will be to have at one's disposal still another species of spirochetes, *Treponema herrejonii* or carateum, to carry out comparative studies with the other two species *Treponema pertenue* and *Treponema pallidum*. One can also foresee that the old debate on the European or American origin of syphilis will flare up again on the basis of the extremely probable fact that Pinto's disease was prevalent in America before Columbus.

It would be extremely useful if the excellent book by Leon y Blanco⁸ could be translated into English, preferably in an enlarged and better illustrated edition.

HUMAN REQUIREMENT FOR THIAMINE

If the science of nutrition is to fulfil its destiny of service to man, the vast collection of fundamental data on experimental animals must be adapted to the needs of man without delay. Even before the Nutrition Conference in 1941, evidence with respect to dietary deficiencies in the nation had been secured. This information was amplified in quantity and implication¹ in 1943. Reliable data must be secured on human requirements for the various dietary essentials. The recommendations made by the Food and Nutrition Board of the National Research Council in 1941 have served as a useful guide in this respect. In the interim active investigation, particularly in the field of the vitamins, has continued in an effort to obtain more adequate criteria for detecting early deficiency states in man and also to improve the analytical methods involved.

Two summaries dealing with the human requirement for the antineuritic vitamin—thiamine, or vitamin B₁—have recently been published. Holt,² in considering the minimum thiamine intake required for the maintenance of health, points out that the composition of the diet affects the requirement of this vitamin. He evaluates the various criteria for adequacy—protection against beriberi, excretion of a definite portion of a test dose of the vitamin, control of the level of pyruvate in the blood, prevention of early accepted signs of deficiency—and concludes that under constant and close dietary control the minimum requirement for the normal human adult is between 0.13 and 0.17 mg per thousand calories. With ordinary food consumption freedom from thiamine deficiency can be

insured by 0.24 to 0.44 mg per thousand calories. It is noted that age, pregnancy, sex and exercise do not materially alter this value for normal persons.

Essentially the same experimental evidence bearing on recent studies of the human requirement for vitamin B₁ has been surveyed by Melnick.³ Various factors operate to give results which differ in the various studies, the nutritional status of the subjects prior to the test, the length of the experimental period and the criteria used for estimating the needs represent variations in technique which bear on the final conclusions. The minimum requirement for the sedentary adult is placed at 0.35 mg per thousand calories. In view of the inevitable losses in cooking and of the uncertainties in absorption and utilization, Melnick considers the current recommendation of the National Research Council, 0.6 mg per thousand calories, "as offering a liberal but necessary margin of safety."

The foregoing discussion calls attention to the complex problem presented by any attempt to evaluate exact human dietary requirements. Despite differences of interpretation of somewhat divergent results, it is clear that such progress has thus far been made as to elicit growing confidence in the estimates currently available.

Current Comment

EFFECT OF AMPHETAMINE SULFATE ON PHYSICAL AND PSYCHIC PERFORMANCE

In Alwall's experiments¹ large groups of soldiers were thoroughly fatigued by two or three nights of marching and exercises during the intervening one or two days, with little opportunity to sleep. In the course of the experiment the men marched 125 kilometers over a partly swampy ground with the temperature of the air being about 41 F. The men slept on an average three and one-fifth hours in the course of the entire experiment. On the termination of the fatigue exercises some of the men were given tablets containing 20 mg of amphetamine sulfate, while others were given placebo tablets. Two and one-half hours later both groups were made to run 3 kilometers. Compared with the initial record established by the two groups just before they were subjected to the fatigue experiment, the postfatigue 3 kilometers run required 95 seconds more for the men given placebos and 18 seconds less for the men given amphetamine tablets. Seventy-one of the men in the amphetamine group of some 250 experienced unpleasant effects from the drug and these men gave a better performance. They were probably more susceptible to the drug, so that the administered dose was for them close to the upper therapeutic limit. The same dose of amphetamine administered after the fatigue period improved the rapidity of reading and

accuracy as determined by the Bourdon test. In persons who were not fatigued 20 mg of amphetamine diminished the ability for solving arithmetical problems. This was particularly true for more difficult and complicated problems than for the easier problems. The same dose administered to fatigued persons at dawn improved the speed and decreased the error percentage in solving arithmetical problems. However, the same tests made in the afternoon no longer exerted a favorable effect, and Alwall believes this due to the fact that fatigue is greatest at about early dawn and decreases in the course of the day, even after a long lack of sleep. The impairment of performance by amphetamine in the daylight tests is not as pronounced in fatigued persons as in the nonfatigued. The condition of the person is important, therefore, in anticipating the amphetamine effect. The same dose may have a favorable effect on the performance under a certain set of conditions and an indifferent or unfavorable effect at another time or under different conditions. A favorable effect is to be expected in the presence of fatigue. The experiments on the effect of amphetamine on marksmanship in target practice in fatigued persons was indecisive but seemed to indicate that amphetamine rather impaired the accuracy of aim in good marksmen.

DIARRHEA AND BACILLARY DYSENTERY

The specific dysenteries and nonspecific diarrheas become a major problem in time of war. Military personnel are not alone involved, however, recently Sandweiss¹ reported observations on 250 civilian patients in Detroit, each of whom had experienced an attack of nausea, vomiting, abdominal cramps and diarrhea. He differentiates the patients into five clinical groups, depending on the severity and duration of their symptoms. Cultures of the stools of 190 of the patients were taken in order to determine whether identifiable pathogenic organisms were responsible for the gastrointestinal symptoms. Twenty-five different strains of paratyphoid or *Salmonella* organisms were isolated in 68 cases. Twenty-seven of the patients were infected with two or three different organisms. Two of the patients died. The outbreak was mild in character, but many of the patients continued to harbor pathogens in their stools for months after the acute episode had subsided. These persons were consequently a hazard as carriers, particularly when employed in food establishments. Sandweiss employed phthalylsulfathiazole (sulfathalidine) for 33 carriers of dysentery organisms. The results were compared with a similar group of 39 patients not so treated. Unfortunately the drug did not appear to influence either the course of the illness or the carrier state, and the results were therefore not conclusive. Indeed, a higher proportion of patients who were treated with the sulfonamide continued as bacillary dysentery carriers than did the untreated patients. A comprehensive preventive program for bacillary dysentery is recommended. This should include the more rigid examination of food handlers with the addition of

routine stool cultures and more frequent follow-up examinations of all carriers. In view of the addition to the population of returning military and civilian personnel, many of whom presumably will be carriers of bacillary dysentery, these recommendations for an intensified preventive program are particularly timely.

CHRONIC ILLNESS IN AN URBAN AREA

The Eastern Health District of Baltimore, which comprises two city wards containing about 11,000 white families and 2,800 colored households, was chosen for a five year survey of chronic illness.¹ This was considered reasonably representative of the type of locality in which an urban wage earning population lives. The following chronic diseases were included: manifest mental disorders, psychoneuroses, psychopathic and personality or behavior disorders, heart disease or hypertension, arthritis, diabetes, varicose veins, gall-bladder disease, peptic ulcer, chronic nephritis, cancer, rheumatic fever, tuberculosis, and syphilis. Out of each thousand persons in the population of 5 years of age and older there were 32 cases of hypertension or heart disease, 18 cases of manifest and subclinical mental disorders, 16 cases of arthritis, 7 cases of rheumatic fever, 6 cases of diabetes and 11 cases of other chronic conditions. This resulted in a total prevalence of these chronic illnesses of 90 per thousand of population. Families chosen because of a case of chronic disease showed an excess rate of illness among its members as compared with the other family groups. The rate of physician visits for these patients with chronic disease was 2,375 per thousand of population or slightly more than two visits per person annually. The rate of clinic visits was 1,517 per thousand, giving a total of about four visits per thousand annually. The same population group had an additional 2.5 visits per person for illness not related to the chronic disorder. Patients with chronic disease, therefore, had from three to four times as much medical care (measured by the number of visits from a physician¹) as did the other members of their families and the general population studied. Persons in the 381 "chronic disease families" formed 26 per cent of the total observed population, had 54 per cent of the total illnesses and received about 50 per cent of the medical care for illness given to the total population. Persons from these few families also constituted almost 40 per cent of the persons hospitalized during the second year of the morbidity study. This interesting report again emphasizes the necessity for sound fundamental studies of the need for and cost of medical care in differently constituted groups. A large part of the medical care problem is the control of the housing, dietary and other environmental factors which affect the development of chronic disease. From the information presented it could be deduced that any plan to spread the cost of medical care over the entire population studied would mean that a comparatively small group and one perhaps especially liable to chronic illness would receive a disproportionate share of the benefits.

MEDICINE AND THE WAR

NAVY

NAVY RESEARCH UNIT DEVELOPS NEW BLACKOUT TENT

An emergency first aid and blackout tent, designed to permit physicians to work after dark in attack zones, was recently developed by the Navy's Medical Research Laboratory, Camp LeJeune, North Carolina. One tent will be issued to each battalion and regimental medical department and one to each medical company. The tent, which is made of neoprene coated balloon cloth, together with its four lines weighs only 6 pounds 15 ounces and enables physicians to maintain blackout conditions when emergency operations must be performed. A flashlight can be used directly on the operative area, and additional light can be obtained by suspending another flashlight from the inside ties. Eight casualties, lying side by side on ponchos or blankets, can be sheltered by draping the tent over them. It will provide satisfactory conditions for examining casualties, securing hemostasis, dressing and redressing wounds and administering plasma.

The Camp LeJeune Medical Field Research Laboratory has also developed a poleless field stretcher, made of nylon weighing less than 7 ounces, which can be carried in large quantities by combat units on extended forays, and an improved hospital corpsman's pouch. Both items will be placed in production soon.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Samuel N Etheredge Jr

Lieut Samuel N Etheredge Jr, formerly of Norfolk, Va, was recently awarded the Bronze Star Medal. The citation accompanying the award read: "For heroic achievement as medical officer attached to a Marine rifle battalion during an engagement with enemy Japanese forces at Piva Forks, Bougainville,

Solomon Islands, on Nov 24, 1943. Constantly subjecting himself to an intense barrage of hostile artillery and mortar fire, Lieutenant (then Lieutenant junior grade) Etheredge fearlessly and courageously established and operated a battalion aid station during a devastating attack by our forces against a strong enemy position. Carrying out his perilous task with outstanding initiative and cool courage, he skilfully ministered to the injured throughout the fierce bombardment and, by his gallant devotion to duty inspired his assistants to remain at their posts despite the extreme danger. Lieutenant Etheredge's outstanding professional ability and personal valor in the face of grave peril were in keeping with the highest traditions of the United States Naval Service." Dr Etheredge graduated from the University of Virginia Department of Medicine, Charlottesville, in 1937 and entered the service Oct 12, 1942.

Lieutenant (jg) Paul H Koren

Lieut Paul H Koren, formerly of Scarsdale, N Y, was recently awarded the Silver Star Medal. The citation read: "For distinguishing himself by gallantry and intrepidity in action as a medical officer of a beach battalion in action against the enemy during the invasion of France, June 6, 1944. Lieutenant (junior grade) Koren engaged in rendering medical aid and attention to the wounded immediately on landing at the water's edge at H plus thirty-two minutes and continued this work regardless of his personal safety throughout D day, exposed himself to the machine gun, rifle and artillery fire of the enemy and inspiring both wounded and unwounded men with confidence by his exemplary action. The conduct of Lieutenant (junior grade) Koren was in accord and keeping with the highest traditions of the United States Naval Service." Dr Koren graduated from New York Medical College, Flower and Fifth Avenue Hospitals, New York, in 1942 and entered the service in June 1943.

ARMY

BRITISH PSYCHIATRIST INSPECTS ARMY FACILITIES HERE

Brigadier John R Rees, consulting psychiatrist to the British army, now in this country as Salmon guest lecturer, visited the Office of the Surgeon General recently where he conferred with the Neuropsychiatry Consultants Division and then inspected neuropsychiatric facilities at Crile General Hospital, Cleveland, and Winter General Hospital, Topeka, Kan. While in Kansas he also participated in the Undersecretary of War's Conference at Fort Leavenworth on "The Military Offender."

Brigadier Rees delivered the annual Thomas W Salmon Lectures at the New York Academy of Medicine, November 20-22 and is now on a lecture tour as guest of the Salmon committee. The Salmon lectures were founded in honor of Col Thomas W Salmon, Medical Corps, who was chief of neuropsychiatry in the first world war.

ARMY MEDICAL CORPSMAN RECEIVES BRONZE STAR

Staff Sergeant Benjamin T Mapes, formerly of New York, was recently awarded the Bronze Star Medal for meritorious achievement in connection with military operations against the enemy in the northern Solomon Islands, July 28, 1943 to July 13, 1944. Sergeant Mapes had been a member of the staff of Willard State Hospital, New York, for sixteen years at the time of his enlistment in the fall of 1942. He was stationed at Fitzsimons General Hospital, Denver, before leaving the States two years ago.

ARMY AWARDS AND COMMENDATIONS

Captain William O Finkelburg

Capt William O Finkelburg, formerly of Winona, Minn, was recently awarded the Bronze Star Medal for meritorious service against the Japanese forces at New Georgia, British Solomon Islands, July 31, 1943." Dr Finkelburg graduated from the University of Minnesota Medical School, Minneapolis, in 1942 and entered the service June 29, 1942.

Lieutenant Colonel Marion R Mobley

Lieut Col Marion R Mobley, formerly chief of the hard of hearing section of Deshon General Hospital, Butler, Pa, was recently commended for especially meritorious service by Major Gen Philip Hayes commanding general of the Third Service Command. The citation read: "for exceptionally meritorious service from May 28, 1943 to July 27, 1944 as chief of the service for the rehabilitation of the hard of hearing established at Walter Reed General Hospital May 28, 1943 and transferred to Deshon General Hospital, Butler, Pa, Nov 1, 1943. Noting the large number of deafened patients requiring treatment and appreciating the limitations of ordinary clinical facilities, Colonel Mobley, by his indefatigable energy, far sighted planning continuous contact with prominent individuals and groups, military and civilian and by designing clinic buildings and facilities, established an ideal program that has been copied in large part by other centers for the hard of hearing. He imbued all who worked with him with his enthusiasm and broad understanding.

As the program grew beyond all expectations, his health finally gave way. Even as a bed patient in the hospital he maintained close advisory contact with the program." Dr. Mobley graduated from the Medical College of the State of South Carolina, Charleston, in 1915, entered the service June 5, 1942 and retired from the Army in September 1944 because of a physical disability.

Captain Sion F. Sherrill

Capt. Sion F. Sherrill, formerly of Belle Fourche, S. D., was recently awarded the Bronze Star Medal for "meritorious services against the Japanese forces at Guadalcanal, British Solomon Islands, Jan. 19, 1943." Dr. Sherrill graduated from the University of Nebraska College of Medicine, Omaha, in 1931 and entered the service April 15, 1941.

Captain Brian J. Gallagher

The Silver Star was recently presented to Capt. Brian J. Gallagher, formerly of Bellerose, N. Y., for bravery and gallantry. The official citation read: "For gallantry in action. On the 1st of April 1943, during the attack by the 3d Battalion, East of El Guettar, Tunisia, Captain Gallagher, while under constant observation by the enemy from high ground, personally supervised the evacuation of the wounded from the field of battle with utter disregard for his personal safety." Captain Gallagher

was active on the front lines, aiding the wounded and exposed himself time after time to enemy machine gun and artillery fire. By his bravery and untiring efforts he saved the lives of a great number of men and his example of steadfast adherence to duties was an inspiration to all men of his detachment." Dr. Gallagher graduated from Long Island College of Medicine, Brooklyn, in 1934 and entered the service in June 1942.

Captain Edward Y. Postma

Capt. Edward Y. Postma, formerly of Grand Rapids, Mich., has been awarded the Bronze Star Medal for meritorious achievement against the enemy. He is serving with the 106th Medical Battalion in the southwest Pacific. Dr. Postma graduated from the University of Michigan Medical School, Ann Arbor, in 1940 and entered the service in July 1942.

Captain Charles S. Becker

An award of the Bronze Star Medal was recently made to Capt. Charles S. Becker, formerly of Jamestown, N. Y. The citation reads: "for meritorious achievement in connection with military operations against the enemy at Bougainville, Solomon Islands, April 6, 1944." Dr. Becker graduated from Western Reserve University School of Medicine, Cleveland, in 1942 and entered the service July 3, 1943.

MISCELLANEOUS

FOUR MEMBERS OF TYPHUS COMMISSION DECORATED

Award of the United States of America Typhus Commission Medal to four members of the commission was recently announced by the War Department as follows:

To Col. Harry A. Bishop, Medical Corps, Medical Section Headquarters Mediterranean Base Section.

'For exceptionally meritorious conduct in the performance of outstanding services from Dec. 28, 1943 to Feb. 19, 1944 at Naples, Italy. Colonel Bishop was placed on duty with the American Typhus Commission at Naples at the height of a typhus epidemic in that city. As coordinating and executive head of its program he directed the training of military and civilian personnel in typhus control, their organization into effectual teams and the securing of needed equipment and supplies. The efficient manner in which this task was accomplished despite the lack of trained personnel and adequate supplies is reflected by the rapidity with which the disease was brought under control. By his forceful leadership and application to duty Colonel Bishop aided materially in alleviating suffering and preventing what might have become a major catastrophe."

To Capt. Edward Harvey Cushing, Medical Corps, United States Naval Reserve.

For meritorious service in connection with the work of the United States of America Typhus Commission. On Captain Cushing, the first executive officer of the commission, fell the responsibilities of administering and directing the work of the commission in the early months of 1943, when the director was invalided as a result of illness. To the contribution which Captain Cushing had made to the planning of the first overseas expedition of the United States of America Typhus Commission he added personal service of high order in his forceful and tactful administration of the activities of the commission during a difficult period at its first station in the Middle East.

To Dr. Alexander G. Gilliam, senior surgeon, United States Public Health Service.

For exceptionally meritorious service in connection with the work of the United States of America Typhus Commission. During the first half of 1943 Dr. Gilliam conducted surveys of typhus fever in Egypt and in Tripoli and made the first field investigations of the efficacy of typhus vaccine among native Egyptians. During the latter part of 1943 he made surveys of typhus fever in India and in China. While engaged in the investigation of scrub typhus fever in Burma, where the disease was assuming high importance as a military problem, Dr. Gilliam suffered a severe attack of this infection. As the first

epidemiologist of the United States of America Typhus Commission Dr. Gilliam contributed expert knowledge and original observations. To his scientific attainments were added qualities of enthusiasm, tact and comprehension which advanced the success of the commission's activities."

To Dr. Fred L. Soper, field staff member of the International Health Division of the Rockefeller Foundation.

For meritorious service in connection with the work of the United States of America Typhus Commission. As one of the original members of the commission, Dr. Soper contributed to the organization of its first expedition to Egypt and to the direction of its first field studies in typhus control. In the latter part of 1943 and early in 1944, as head of the Rockefeller Foundation group in Italy, he cooperated with the United States of America Typhus Commission in stopping the outbreak of typhus fever at Naples. Dr. Soper placed at the service of the commission his many years of distinguished service in the administration and operative control of epidemic diseases.

VETERANS REHABILITATION CENTER

The Veterans Rehabilitation Center (2449 West Washington Boulevard, Chicago), operated jointly by the Department of Public Welfare, State of Illinois and the Illinois Veterans Service Inc., was formally dedicated November 3. The center has been receiving World War II veterans for treatment of selected psychiatric disorders since Sept. 11, 1944. The existing floor plan of the Washington Boulevard Hospital was utilized, operating rooms, wards, more desirable single rooms and adjoining hospital grounds were equipped and refurnished for use as arts and crafts rooms, recreational rooms, drama rooms, music rooms, gymnasium and gymnasium grounds.

All projects are under the supervision of full time specialists, who are assisted by qualified volunteers. The present treatment capacity of the center is 100 patients which may easily be expanded to twice that number by slight increases in specialist personnel. Thirty beds are available for those veterans requiring psychiatric nursing supervision. It is anticipated that the majority of the veterans under treatment will live in their own homes or in suitable living quarters provided for them outside the center.

The psychiatric staff of the center consists of Dr. Alfred P. Solomon, clinical director, Dr. Thomas L. Fentress, associate clinical director, Dr. David Slight, professor of psychiatry at the University of Chicago, Dr. Clarence Neymann, professor of psychiatry at Northwestern University Medical School, and Dr. Morris Braude, associate professor of psychiatry at the University of Illinois College of Medicine. The clinical director

works in close cooperation with Dr Conrad Sommer, deputy director of mental hygiene, Department of Public Welfare, State of Illinois. Dr Sommer was responsible for the development of the initial plans for the center.

Each of the staff members has the responsibility of patients assigned to him for treatment either in individual or in group psychotherapy, and the supervision of one department of the activity program. The activity program has two major functions, diagnostic and therapeutic.

Shortly after the veteran has been introduced to the activity program, his work habits, his attitudes toward work and play, his vocational interests and antipathies, his skills and aptitudes and the character of his human relationships become apparent. These clinical observations, combined with the psychiatrist's study of the patient, the social service record and the results of psychologic testing, provide the basis for the adjustment of the activity program to the needs of the patient.

Activities are prescribed in the same manner as the orthopedic surgeon prescribes specific exercise for an extremity to encourage restoration of an impaired function. In the prescription of an activity designed to alter behavior, it is necessary that the psychiatrist orient the activity therapist as to the nature of the patient's emotions, his character traits and problems, so that the therapist will know the appropriate attitude to assume toward the patient. Furthermore, the psychiatrist must be aware of the possibilities for psychologic use of each activity so that, combined with the control of the human relationship factor, he is in position to direct development of qualities in the personality with the same degree of specificity with which he can direct development of the biceps muscle.

The function of the inpatient department of the Rehabilitation Center is planned for the treatment of psychoneurotic patients who do not require active medical and surgical care or psychiatric isolation and protection procedures. A primary consideration in all admittances is group morale. For this reason the right is reserved to reject for admittance or to discharge from the hospital any patient whose behavior might disrupt the morale of the group. Patients with physical disabilities that do not require medical or surgical treatment are eligible for admission and treatment of their psychoneuroses. Patients with organic diseases of the central or peripheral nervous system, excluding epilepsy and severe migraine, are eligible for admission if they have psychoneuroses and do not require neurologic care. Patients with psychoneurotic depressions will be accepted for treatment with the reservation that any patients who prove to be suicidal risks may be discharged or refused admission as the Rehabilitation Center is not prepared to give them the necessary care and protection. The mildly schizophrenic who have made a social adjustment and who show no tendency toward overt hostile behavior will be accepted for treatment. No provision has been made to accept for admission patients with paranoid trends or delusions. Certain carefully selected patients with psychopathic personalities or alcoholism will be accepted for treatment if these patients are believed to have a sufficiently hopeful prognosis for a group adjustment. Patients are referred directly to the center, or arrangements are made for admission by a referring agency.

At the dedication of the Veterans Rehabilitation Center Dr Alfred P. Solomon gave an address on 'Activity Therapy at the Veterans Rehabilitation Center', Dr Herman L. Kretschmer gave an address on 'Mental Rehabilitation on a State Level'. An address on 'Men Back from Wars' was given by Col William C. Porter, U. S. Army Medical Corps.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced.

McGuire General Hospital, Richmond, Va. Shock, Capt William A. Weiss, Burns, Dr E. I. Evans, December 22.

Regional Hospital Langley Field, Va. Rheumatoid Arthritis, Dr T. Dewey Davis. Cardiovascular Diseases, Dr Douglas G. Chapman, December 29.

Newton D. Baker General Hospital, Martinsburg, W. Va. Final Results of Intervertebral Disk Operations, Dr Walter E. Grundy. The Development of Plastic Surgery in World Wars I and II, Dr John Sturge Davis, December 18.

Deshon General Hospital, Butler, Pa. Colostomy and Its Complications, Dr Verne A. Dodd, December 19.

Air Base Hospital, Patterson Field, Dayton, Ohio. Diagnosis and Treatment of Pneumonia with Emphasis on Primary Atypical Pneumonia, Dr B. K. Wiseman, December 20.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service.

(Continuation of list in THE JOURNAL, December 9, page 967)

CALIFORNIA

Permanente Foundation Hospital, Oakland. Capacity 136 admissions. 3,693. Dr Sidney R. Garfield, Superintendent (interns, July 1945).

NEW YORK

New York Post Graduate Medical School and Hospital, New York. Capacity 409 admissions. 8,622. Dr William H. Meyer, Director of Radiology (1 resident—radiology, early in 1945).

Crouse-Ingling Hospital, Syracuse. Capacity 245 admissions. 7,035. Miss Dorothy Pellenz, Assistant Superintendent (interns).

OHIO

St. Thomas Hospital, Akron. Capacity 235 admissions. 7,405. Sister M. Eleanor R.N., Superintendent (2 interns, Jan. 1, 1945).

MEDICAL AID FOR DEPENDENTS OF SERVICE MEN

The North Atlantic area of the American Red Cross has adopted a plan providing for admission of 'a limited number' of service men's dependents to voluntary hospitals without involved investigations of their financial status. The plan developed by Brig. Gen. Ralph K. Robertson of the Second Service Command, provides that the city pay \$3.25 a day for each patient, the private hospital making up the rest. No money is required from the Red Cross. Mr. E. Roland Harriman, manager of the North Atlantic area, stated that 'the voluntary hospitals have been most generous for years in the admission of large numbers of service men's dependents referred to them by Red Cross chapters. A similar cordial cooperation has been given by the city hospitals and the Department of Welfare. The new plan, Mr. Harriman said, will create 'a slight difference of emphasis which will make the service of voluntary hospitals more readily available'. Proof only of dependency and medical indigence will be required for admission, eliminating the investigation usually made for 'charity cases'.

GERMANS FEAR SHORTAGE OF DOCTORS

The shortage of doctors in Germany has reached a new low. There are only 35,000 doctors, including those on duty with the armed forces, at the disposal of the 80,000,000 Germans living in Germany, according to the Swiss newspaper *Schaffhauser Arbeiterzeitung*.

In an article reported recently to the Office of War Information, the Swiss newspaper said that official Nazi quarters admitted the "rapid increase of tuberculosis" and the "frightening way the number of miscarriages is mounting" as well as the appearance of several other diseases such as 'different chest and skin diseases'.

"National Socialist circles follow this development with great anxiety, especially since the Third Reich lacks not only doctors but also medicines," the Swiss paper said, adding that this decline of the German people's health was the logical result of 'bad and quantitatively insufficient nutrition'.

EPIDEMIC OF RABIES IN VIENNA

An epidemic of rabies, believed to have started among German army dogs in the garrison on the outskirts of Vienna about a month ago, is raging in the city and deaths are reported to be assuming alarming proportions particularly among the civilian population. Austrian authorities are enlisting the aid of both press and radio to warn the population in an effort to circumscribe the outbreak. The Vienna radio announced recently that 43 dogs had been shot in the city.

ORGANIZATION SECTION

Postwar Medical Service

A meeting of the Committee on Postwar Medical Service was held October 28 at the headquarters office of the American Medical Association in Chicago. The meeting was called to order by the Chairman, Dr Roger I Lee. The following persons were present:

Dr Roger I Lee Boston Chairman
Lieut Col Harold C Lueth Chicago
Dr Ernest E Irons Chicago
Brig Gen Fred W Rankin Washington D C
Dr Everts A Graham St Louis
Rev A M Schwitalla St Louis
Dr Irvin Abell Louisville Ky
Dr Francis F Borzell Philadelphia Central Committee Wartime Graduate Medical Meetings
Dr J F Hassig Kansas City Kan Federation of State Medical Boards
Mr Graham L Davis Battle Creek Mich American Hospital Association
Dr R C Williams Washington D C U S Public Health Service
Col Hugo Mella Washington D C Veterans Administration
Dr Francis G Blake New Haven Conn
Dr Frederick A Collier Ann Arbor Mich
Dr James M Mason Birmingham Ala
Dr Walter W Palmer New York
Capt William E Eaton (MC), U S Navy
Dr Morris Fishbein Chicago
Dr Arthur W Allen Boston
Dr Edwin P Jordan Chicago
Lieut Col Gerard R Gessner Washington D C
Col George M Powell Washington D C
Dr Herman L Kretschmer Chicago
Dr James E Paullin Atlanta Ga
Dr Victor Johnson Chicago
Dr H H Shoulders Nashville Tenn
Mr E R Love and Philadelphia
Mr J W Holloway Jr Chicago
Dr Olm West Chicago
Dr R L Sensenich South Bend Ind
C Willard Camaler D D S Washington D C
Miss Mary Switzer Washington D C Procurement and Assignment Service
Dr Frank H Lahey Boston Directing Board Procurement and Assignment Service
Dr Harold S Diehl Minneapolis Directing Board Procurement and Assignment Service
Dr Harvey B Stone Baltimore Directing Board Procurement and Assignment Service
Miss Louise V Baker Washington D C Procurement and Assignment Service
Dr Paul C Barton Washington D C Procurement and Assignment Service

In the absence of the Secretary Dr Alan Gregg the Chairman appointed Dr Ernest E Irons Secretary pro tem.¹

The minutes of the last meeting of the Committee were approved as circulated. The Chairman read the letter of resignation of Dr Willard C Rappleye in which he stated that he resigned as representative of the Association of American Medical Colleges, being no longer an officer of the Association of American Medical Colleges or of the Advisory Board for Medical Specialties. This resignation was accepted. The Secretary pro tem was directed to request the Association of American Medical Colleges and the Advisory Board for Medical Specialties to name representatives to this Committee. (These requests have been forwarded to the secretaries of the aforementioned organizations.)

The Committee then proceeded to the consideration of the subcommittee reports.

A Lieutenant Colonel Lueth reported on the progress of the tabulation of replies to the questionnaire sent out through the Surgeons General to the medical officers in the three services. Copies of these reports were submitted to the members. This subcommittee was continued.

B The Subcommittee to Confer with the Surgeons General Dr Frederick A Collier, Chairman Dr Walter W Palmer, Rev A M Schwitalla, Dr Victor Johnson and Lieutenant Colonel Lueth. Dr Collier reported for the subcommittee that he, Dr Palmer and Father Schwitalla had conferred with the Surgeon General of the U S Army regarding in service training and problems of demobilization. The subcommittee was asked to continue its work and at as early a date as possible to obtain a conference with the Surgeons General of the U S Navy and of the U S Public Health Service. The report of the subcommittee was received with thanks and the committee continued.

C The relation of the Committee on Postwar Medical Service to the Procurement and Assignment Service was discussed at length. The directing board of the Procurement and Assignment Service has stated that it is its recommendation that Procurement and Assignment terminate with the termination of the war and that its records belong to the government. They would be quite willing to turn these records over but have no power, since the records are government property. Dr Paullin stated that there was much information available in state and local groups which would be valuable in postwar medical demobilization and postwar medical educational plans. Dr Stone suggested that the Committee on Postwar Medical Service might well look into the question of utilization of the knowledge and experience of state chairmen and their committees on Procurement and Assignment with a view to using their information for the assistance of returning medical officers.

The following subcommittee was appointed to draw up a report on the relation of the Committee on Postwar Medical Service and the Procurement and Assignment Service. Dr Ernest E Irons, Chairman, Dr Morris Fishbein, Dr Harold S Diehl, Dr Victor Johnson and Lieut Col Harold C Lueth. This subcommittee is to submit a report at the next meeting of the Committee on Postwar Medical Service.

D Capt William E Eaton for the Medical Corps of the Navy discussed the role of refresher courses in the training of medical officers. The possibilities and limitations of suggested resident training in army and navy hospitals were discussed.

E Problems of the Veterans Administration with respect to medical personnel were discussed. Father Schwitalla suggested that the legal questions involved in the possible establishment of a medical corps in the Veterans Administration be investigated. (The Chairman later appointed as a subcommittee to investigate and report, Rev A M Schwitalla, Chairman, Dr H H Shoulders, Dr Le Roy H Sloan.)

F Dr Francis F Borzell for the Central Committee of the Wartime Graduate Medical Meetings during the discussion emphasized the great contribution which the Wartime Graduate Medical Meetings have made to the medical aspects of the war effort. Dr Borzell indicated the desire of the Central Committee to cooperate in any and all ways with the Committee on Postwar Medical Service. It was pointed out that the armed services would prefer to clear problems through one organization rather than through several. It was therefore agreed that the suggestion of Dr Borzell and his committee be approved and that hereafter the Wartime Graduate Medical Meetings committee will clear through the Committee on Postwar Medical Service.

G Lieut Col Harold C Lueth reported on the activities of the Bureau of Information for medical veterans. The activities of this Bureau will include (1) informational service on educational questions (2) state licensure and (3) relocation. Prospective desires and requirements of returning medical officers having now been approximately determined by the returned questionnaires, the problem now is to determine where the facilities can be obtained. A new questionnaire directed to hospitals and medical educational institutions has now been prepared through the Council on Medical Education and Hospitals under

¹ The minutes of the meeting were taken by stenotype and are available for reference by members of the Committee. It was felt however that a brief summary of the Committee actions should be presented here in an abbreviated form. It should also be noted that certain items of importance do not appear in the stenotype records.

the direction of Dr Victor Johnson and Lieutenant Colonel Lueth This questionnaire is now being sent to hospitals, medical institutions and others, and it is hoped that a more complete knowledge of available facilities will shortly be obtained Many medical officers have indicated their intention to return to their former residences Others have indicated their intention to change their locations The Bureau of Information of the American Medical Association plans to be of service to the latter group, furnishing information but not acting as a placement bureau The cooperation of state and county units will be an important factor in the effectiveness of this bureau

H Dr J F Hassig, representing Dr Walter L Bierring for the Federation of State Medical Boards, was asked to report on the recent recommendation for a uniform licensing law for temporary licenses Dr Hassig reported that the Federation thus far had no formal action to report

I Dr Roger I Lee reported on certain proposed voluntary lay funds to be used for postwar medical education of returning medical officers At the moment such plans had not sufficiently materialized for formal report

J Dr Victor Johnson reported for Dr Walter W Palmer for the Subcommittee on Postwar Residencies The draft of the questionnaire sent to approved hospitals had been prepared to secure information on available residencies and on the possibility of extension of such residencies by hospitals

K Father Schwitalla reported for the information of the Committee that the Association of American Medical Colleges had laid on the table the proposal for bringing internship into the purview of the college curriculum

L It was reported that certain medical schools have been asked to submit lists for release from the medical departments of the armed services of desired and needed faculty teacher members

The Committee adjourned to meet Saturday, Dec 9, 1944 at 10 a m at 535 North Dearborn Street, Chicago

ERNEST E IRONS, M D, Secretary Pro Tem

Official Notes

THE PHILADELPHIA SESSION

Section Representatives to the Scientific Exhibit

Each section of the Scientific Assembly has appointed a representative to the Scientific Exhibit to assist and advise in securing exhibits for the Philadelphia session, June 18-22, 1945 The following physicians have received these appointments

Practice of Medicine—Thomas C Garrett 3803 Oak Road German town Philadelphia
Surgery General and Abdominal—Owen H Wangenstein University of Minnesota Medical School Minneapolis
Obstetrics and Gynecology—Frederick H Falls 1853 West Polk Street Chicago 12
Ophthalmology—Georgiana D Theobald 120 Medical Arts Building Oak Park Ill
Laryngology Otology and Rhinology—Paul H Holinger 700 North Michigan Avenue Chicago 11
Pediatrics—W Ambrose McGee 1601 Monument Avenue Richmond Va
Experimental Medicine and Therapeutics—Robert W Wilkins Evans Memorial Hospital 65 East Newton Street Boston
Pathology and Physiology—F W Konzelmann Atlantic City Hospital Atlantic City N J
Nervous and Mental Diseases—F P Moersch Mayo Clinic Rochester, Minn
Dermatology and Syphilology—Hamilton Montgomery 102 Second Avenue SW Rochester Minn
Preventive and Industrial Medicine and Public Health—Paul A Davis 1436 Delin Avenue Akron Ohio
Urology—John H Morrissey 40 East Sixty First Street New York
Orthopedic Surgery—David M Bosworth 742 Park Avenue New York 21
Gastroenterology and Proctology—Grant H Laing 104 South Michigan Avenue Chicago
Radiology—S W Donaldson 326 North Ingalls Street Ann Arbor Mich
Anesthesiology—Urban H Eversole 605 Commonwealth Avenue Boston

Washington Letter

(From a Special Correspondent)

Dec 11, 1944

Army Needs 14,000 More Nurses

A pledge that men in the Army, Navy and Veterans hospitals will receive good nursing care was given by the National Nursing Council for War Services at its first Washington meeting, held in the Social Security Building here with some fifty representatives of governmental and voluntary nursing agencies present Mrs Elmira B Wickenden, executive secretary, said that more than 50,000 out of a profession with 265,000 active members had already volunteered in spite of home front needs but that 14,000 more nurses are needed by the Army They will be found, and "until military quotas are met civilian needs will be secondary," she said Steps taken to recruit more nurses for military service include an appeal by Representative Francis P Bolton (Republican, Ohio), sponsor of the act creating the U S Cadet Nurse Corps, emergency conferences in large cities, including Baltimore, Boston, Brooklyn, Newark, Philadelphia and San Francisco, review of nurses classified by the Procurement and Assignment Service Committee, employment of graduate nurses on a civilian basis by army hospitals, and cooperation of the Army, the Navy, the Office of War Information and the War Advertising Council on Publicity Miss Stella Goostay, principal of Children's Hospital School of Nursing, Boston, presided

Extension of Recreational Facilities Urged

Provision of adequate recreational facilities for the war period and their extension after the war to meet increased peacetime necessities were urged at a conference of the War Recreation Workers Association held in the East Room of the White House Mrs Roosevelt expressed the opinion that our experience during the "bad economic situations" of the thirties should be a warning against permitting lack of coordinated recreational programs to affect the younger generation Miss Ruth Green presided, and problems were discussed by Mrs Roosevelt, Capt Mildred McAfee, U S N R, Mark McCloskey, director of Community War Services, Miss Helen Rowe, chairman, American Association for the Study of Group Work, Roy Sorenson, association general secretary, National Council, Y M C A, and John I Neasmith, Federal Security Agency

President Roosevelt Endorses 1945 Poliomyelitis Drive

President Roosevelt has approved the request of Basil O Connor, president of the National Foundation for Infantile Paralysis, to launch the foundation's 1945 fund raising drive on his next birthday, January 30 Mr O'Connor announced that the 1945 march of dimes to the White House will be held from January 14 to January 31 In dedicating his birthday for the twelfth year to the fight against poliomyelitis the President said "The fight against infantile paralysis is a fight to the finish and the terms are unconditional surrender" He added "We face formidable enemies at home and abroad Victory is achieved only at great cost, but victory is imperative on all fronts"

Capital Dentists Honor Horace Wells

On the 100th anniversary of his discovery of the principles of anesthesia, Horace Wells was honored by the District of Columbia Dental Society with the unveiling of a bust of Wells in the Medical Society Auditorium During the ceremony several speeches were delivered on modern anesthesia, with leading medical men of the Capital, including military and governmental officials, taking part

Eleven General Hospitals Needed at the Front

Col Florence Blanchfield, superintendent of the Army Nurse Corps, has announced that eleven general hospitals must be established on the European front immediately and that nurses will be required to staff them She said that men who are wounded or ill are returning from the battle fronts at the rate of 12,000 a week and require the care of 14,000 mo

Safety Conditions in Federal Service Probed

A bill providing funds for the U S Employment Compensation Commission to investigate safety conditions in the civil service, which are described as far below those in private industry, has been reported out by the Senate Education and Labor Committee. The casualty report of the commission for the first half of 1944 shows a rise in frequency of occupational disabilities from 13 to 132 per cent per million man-hours worked. Average cost per federal employee is now \$4.48 a year in benefit payments for accidents on the job.

Rats Menace Nation's Capital

Infestation of Washington by rats, which has made many District of Columbia dwellings unfit for habitation, is causing growing concern here. Major William H. Cary Jr., District director of sanitation, has called on District residents to help combat the city's estimated million rat population. The health department has only one experienced inspector and thirty assistants in spite of about twenty thousand complaints being received annually.

Medical Legislation

DISTRICT OF COLUMBIA

Changes in Status—H R 2644 has passed the House and Senate, granting additional powers to the Commissioners of the District of Columbia, including the authorization to waive the payment by any person in the military service of any annual or other periodic fee required by the law to be paid to the District of Columbia as a condition to retaining or renewing any license or permit to engage in any business or calling or to practice any profession. H R 3150 has passed the House and Senate, proposing to amend the healing arts practice act so as to eliminate the requirement that an applicant applying for a license without examination must have practiced the healing art under a license obtained in another jurisdiction for not less than two consecutive years immediately preceding the date of his application for his license in the District. As a substitute for this requirement the bill provides that the applicant must have practiced the healing art after the issuance of the license obtained in another jurisdiction for not less than one continuous year out of three years immediately preceding the date of his application for license in the District. This bill provides that the required one continuous year's practice may be either private, institutional or governmental, or a combination thereof. H R 3619 has passed the House and Senate, amending the act regulating the disposal of dead human bodies in the District. This bill provides for the appointment of deputies who will be authorized to issue permits for the removal of dead bodies from place to place within the District and for the recognition of foreign burial permits by superintendents and other persons in charge of cemeteries in the District. H R 4867 has passed the House and Senate, extending the health regulations of the District of Columbia relating to restaurants to similar establishments operated by the government.

MEDICAL BILLS IN CONGRESS

Changes in Status—S 2201 has been reported to the Senate, providing for promoting and maintaining the physical and mental fitness of employees of the federal government. This is a companion bill to H R 5257 which is pending in the House of Representatives with a favorable committee report. H R 4216 has been reported to the House providing more efficient dental care for the personnel of the United States Navy. A special rule has been granted on this bill by the House Committee on Rules which assures early consideration. The bill is designed to accomplish its objective largely through a change in administrative practices and procedures which will place professional, technical and administrative dental matters in the hands of dental officers and will make the senior dental officer on ships and

shore stations directly responsible to the commanding officer in this connection. H R 5587, the First Supplemental Appropriation Bill, 1945, has passed the House. Among other things, this bill makes available to the Veterans Administration the sum of \$10,571,000 for hospital and domiciliary facilities. It also includes appropriations for the United States Public Health Service, including \$963,400 for the pay of personnel and maintenance of hospitals and \$1,875,000 for emergency health and sanitation activities. The latter appropriation will be used in connection with three projects, namely (1) plague control in the Hawaiian Islands of Maui and Hawaii, for protection of military personnel, (2) the conduct of antimalarial projects in centers of malaria transmission in a number of states for the purpose of meeting the impact of returning carriers among servicemen and (3) sanitary measures in Liberia primarily for the benefit of citizens of the United States, military and civil, stationed in or passing through that country. The House Committee on Appropriations refused to provide an appropriation of \$205,000 for the Public Health Service for postwar planning and an appropriation of \$773,000 for the control of tuberculosis. The committee thought that both of these projects should be given consideration in connection with a regular appropriation bill.

Bills Introduced—S J Res 163, introduced by Senator Davis, Pennsylvania, proposes that Congress shall give recognition to the fact that the success of the Selective Service System has been in a great measure due to the service of members of local draft boards and other persons who have served voluntarily and without compensation. S 2148 introduced by Senator Kilgore, West Virginia, proposes to amend the Servicemen's Readjustment Act of 1944 to provide that the education and training to be had under that act shall be available to veterans without regard to their age and irrespective of whether or not their education or training was impeded, delayed, interrupted or interfered with by reason of entrance into the service. S 2191, introduced by Senator Langer, North Dakota, and H R 5454, introduced by Representative Springer, Indiana, propose to amend the laws relating to veterans so as to eliminate the requirement that certain applicants for hospital treatment or domiciliary care shall take the pauper's oath. H R 5426, introduced by Representative Bolton, Ohio, H R 5431, introduced by Representative Norton, New Jersey, and H R 5432, introduced by Representative Smith, Maine, propose to incorporate the Medical Women Army-Navy Club. The objectives and purpose of the corporation will be, among other things, to endow a memorial to honor nurses of the Army and Navy who served as officers in World War II and to engage in activities for the promotion of the general welfare of the women commissioned officers of the Medical Departments of the Army and Navy. H R 5487, introduced by Representative Fish, New York, proposes to amend the National Cancer Institute Act so as to authorize an appropriation of \$10,000,000 each fiscal year, beginning with the termination of hostilities with Germany, for the purpose of carrying out the provisions of that act.

Society Proceedings

COMING MEETINGS

- Annual Congress on Industrial Health Chicago Feb 13-15 Dr Carl M Peterson 535 N Dearborn St Chicago Secretary
- Annual Congress on Medical Education and Licensure Chicago Feb 12-13 Dr Victor Johnson 535 N Dearborn St Chicago Secretary

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Special Lecture—Dr Arthur C De Graff, Samuel A Brown professor of therapeutics, New York University College of Medicine, will address a special meeting of the San Francisco County Medical Society and the San Francisco Heart Committee, December 18, on 'Present Status of Digitalis and the Cardiac Glucosides in the Treatment of Congestive Heart Failure.'

Free X-Ray Service—An x-ray chest survey center was recently opened in San Francisco in the building of the city department of health and operated by the San Francisco Tuberculosis Association in cooperation with the local health department. The equipment was purchased with funds raised from the sale of Christmas seals. The center will provide free x-rays to the public five days each week and, when in full operation, will be capable of examining about 250 persons a day.

Plague and Tularemia—*California's Health* reports that in September bubonic plague had been demonstrated in a pool of 164 fleas taken from 35 ground squirrels collected on a ranch in Kern County. During the same month, a pool from 4 ground squirrels collected on a ranch in Lassen County proved positive for plague. During the same month, six pools of fleas taken from squirrels on two ranches of San Luis Obispo County proved positive for plague. Tularemia was demonstrated in a pool of 16 ticks taken from ground squirrels on a military reservation in Monterey County. Tularemia was also demonstrated in eight pools of mice taken within 5 miles of San Luis Obispo City.

CONNECTICUT

State Society Opens Membership to Students—On December 7 the house of delegates of the Connecticut State Medical Society adopted an amendment to its by-laws providing that any person whose legal or family residence is in the state of Connecticut who is a regularly enrolled student and a candidate for the degree of doctor of medicine in an acceptable medical school, as provided in section 478F of the Cumulative Statutes of Connecticut, or any person who is a student in an acceptable medical school located in the state of Connecticut may become a student member of the society. Also physicians not licensed to practice medicine in Connecticut who are serving as interns or residents in hospitals in Connecticut, for the purpose of extending their education and not primarily for remuneration, may become student members of the society. Such membership shall be obtained by applying to the council of the society on a form provided for that purpose and election by vote of a majority of the council. Student members will enjoy all the rights and privileges of membership in the society except that they shall not be eligible to vote or hold office. When such a student member is licensed to practice medicine in the state of Connecticut and settles in this state in practice or remunerative employment, he shall be eligible at once for election to active membership in the county association in the county in which he has settled without the waiting period of residence within the county, subject to such regulations as may be imposed by such county associations.

DISTRICT OF COLUMBIA

Action on "Borderline Certificates" Criticized—The executive board of the Medical Society of the District of Columbia recently stated that the action of the Board of Medical Examiners of Maryland in discontinuing issuance of 'borderline certificates' to physicians licensed in Washington 'cannot be justified' and called on residents of nearby Maryland counties to make themselves heard in the matter. The certificates cost \$1 and legalize the practice of medicine in Maryland by physicians licensed in the District of Columbia. Newspapers reported that some time prior to November 15 Dr George C Ruhland, District health officer, learned that no new borderline certificates would be issued. In a statement to the press the executive board of the District society said it is 'unreasonable' to ask busy District physicians to spend a day making the trip to Baltimore to get a full license

to practice in Maryland. The certificates are issued through the mail. Many county residents come in to the office of Washington physicians for treatment and when they are all at home "naturally expect to call physicians who have cared for them in their offices." If the present ruling of the board is enforced, it was stated, this will not be possible in a great many instances until these physicians have obtained the required (full) licenses. These cost \$50 each. "The present arrangement under which reciprocal borderline certificates are issued has been in effect many years. To scrap it in the midst of a war and in the face of a shortage of physicians cannot be justified. Certainly the people should make themselves heard, for it is they who are most vitally affected," the board said.

IDAHO

Society News—Dr Archibald L Hoyne, Chicago, discussed the 'Management of Contagious Diseases in General Practice' at the October 18 meeting of the North Idaho District Medical Society in Lewiston. Dr Hoyne, among others, also addressed the Southwest Idaho District Medical Society in Boise recently.

ILLINOIS

Free Antipneumonia Serum to Be Discontinued—Effective January 1 the Illinois State Department of Public Health will discontinue the free distribution of antipneumococcic serum. This action is being taken with the approval of the pneumonia advisory council of the department and the council of the Illinois State Medical Society. At the time free distribution of antipneumococcic serum was begun by the Illinois State Department of Public Health in 1937, no other specific form of therapy was available, and the wide use of serum resulted in a pronounced decline in the case fatality rate of pneumonia. Since then however, the discovery and introduction of new sulfonamide compounds such as sulfathiazole and sulfadiazine have provided a simpler and more economical therapeutic agent for this disease. Carefully controlled studies have shown that the treatment of pneumonia with sulfonamide drugs is equal, if not superior, to treatment with serum. The availability of penicillin for civilian use has provided an additional highly potent method of treatment where indicated. Sulfathiazole and sulfadiazine for the treatment of pneumonia may be had on request from the division of communicable diseases, all full time local health departments and all approved pneumonia typing laboratories.

CHICAGO

Personal—Dr Jacob V Edlin has been given a leave of absence on account of ill health from his position as superintendent of the Chicago State Hospital. Dr Frank J Griffin is acting superintendent.

The McArthur Lecture—Dr Arnold R Rich, associate professor of pathology, Johns Hopkins University School of Medicine, Baltimore, will deliver the twenty-first Lewis Linn McArthur Lecture of the Frank Billings Foundation at the Palmer House, February 23. His subject will be "Role of Hypersensitivity in the Pathogenesis of Rheumatic Fever and Periarthritis Nodosa."

Meeting on Industrial Medicine and Surgery—The Central States Society of Industrial Medicine and Surgery held its midwinter scientific meeting at the Palmer House, December 8, under the presidency of Dr Fred M Miller. In addition to clinics at St Luke's and Cook County hospitals, speakers on the program included Dr Walter S Priest on "Penicillin Therapy in Relation to the Problems of Industrial Medicine and Surgery." The program also included a panel discussion on "Fixations of Fractures" and one on "Head Injuries."

IOWA

Personal—Dr Gisle M Lee Thompson, was guest of honor at a banquet given by the Thompson Commercial Club, October 16, in recognition of the community's appreciation for his fifty years' service. He was presented with a silver gift in the form of one dollar for each year of service to the community—Avery E Lambert, Ph.D., professor of histology at State University of Iowa College of Medicine, Iowa City, who has been connected with the school since 1925 has reached the age of retirement but will continue some of his work on a part time basis.

First Tuberculosis Case Register—The first central tuberculosis case register in Iowa was recently installed at Sunny Crest Sanatorium, Dubuque. The project which was made possible through the efforts of the Dubuque County Tuberculosis Association, the staff of the sanatorium the

Visiting Nurse Association and county and school nurses will provide current information on the location of known patients in the county, the status of the disease and the treatment being received. It will guide health officials in administering the tuberculosis control program which has been functioning for a number of years.

Blank Memorial Hospital Dedicated—On December 3 the new \$300,000 Raymond Blank Memorial Hospital for Children Des Moines, was dedicated. The hospital said to be the first in Iowa constructed exclusively for the treatment of children is the gift of Mr and Mrs A H Blank, Des Moines and is a memorial to their son, Raymond, who died March 7 1943 at the age of 32. The hospital adjoins the Iowa Methodist Hospital. Among the speakers at the dedication were Dr Walter L Biering, Des Moines, state health commissioner and Dr Morris Fishbein, Editor of THE JOURNAL. Mr Blank made the presentation of the hospital and the acceptances were given by Rolfe O Wagner, president of the board of directors Iowa Methodist Hospital, for the hospital and Gov Bourke B Hickenlooper for the people of Iowa.

KENTUCKY

New Director of Industrial Hygiene—Dr Wayne L Ritter, U S Public Health Service, has been named director of the bureau of industrial hygiene of the Kentucky State Department of Health to succeed Dr Walter E Doyle, who was recently called to Washington D C (THE JOURNAL, October 7 p 379).

Personal—Dr William L Cash, Princeton, examining physician for the Caldwell County Selective Service Board was recently presented with an embossed certificate for patriotic service following three years of duty with the draft board. The certificate is signed by President Roosevelt, Major Gen Lewis B Hershey director of Selective Service, Gov Simeon S Willis and Col Frank D Rash, state director of selective service.—Dr Isham Kimbell has resigned as head of the Central State Hospital, Lakeland to become a member of the staff of the Veterans Administration Facility Fort Lyon Colo effective October 31.

MAINE

Society News—Dr Ralf S Martin, Portland, addressed the York County Medical Society in Kittery, October 11 on 'Recent Advances in Rheumatic Fever'. Other speakers included Dr Adam P Leighton Portland president-elect of the Maine Medical Association, who discussed the opening of a medical school in the state.—Dr Edwin H Place Boston discussed "Contagious Diseases and Complications" before the Penobscot County Medical Association in Bangor October 17.

MASSACHUSETTS

Session on Obstetrics—The sixteenth annual meeting of the New England Obstetrical and Gynecological Society was held at the Harvard Club Boston, December 6, under the presidency of Dr Roy J Heffernan, Brookline, whose address was titled "Role of the Transverse Cervical Cesarean, and the Management of Placenta Previa". Among the speakers were:

Dr Louis E Phaneuf Boston The Repair of the Lacerated Perineum
Dr Maurice O Belson Boston Management of the Third Stage of Labor
Dr Meyer D Schnall Boston Sternal Transfusions in Obstetrics and Gynecology
Dr Joe V Meigs Boston Ureter in Pelvic Surgery
Dr Harold H Rosenfield Boston Report on Obstetric Analgesia
Dr George W Waterman Providence R I Committee's Report Concerning the Emergency Maternal and Infant Care
Dr C Wesley Sewall Boston Experience with the Rh Factor from the Obstetric Viewpoint
Dr John M Fallon Worcester Photographic Clinic

Bureau of Clinical Information Formed—The Massachusetts Medical Society has established a bureau of clinical information as a means of augmenting its postgraduate educational effort. The bureau will supply information on the daily activities of approved hospitals in Boston and its immediate vicinity covering each hospital's schedule of operations for the day, medical and surgical ward rounds clinics, the location of such clinics and the names of those presiding over these various activities. From time to time the bureau will make available a bulletin which will list the fixed medical meetings and conferences held in the metropolitan area. This bulletin will be sent to hospitals medical schools and physicians on request and will be available at the bureau. The bureau will be open from 7 to 10 a m and from 3 to 8 p m except Saturday afternoons. Information will be given by telephone. No expense is involved on the part of those using this service.

MINNESOTA

Illegal Practitioner Sentenced—On October 27 Frank J Brady, alias Frank Bateman, pleaded guilty in the district court of Hennepin County to a charge of practicing healing without a basic science certificate and was sentenced to a term of one year in the Minneapolis workhouse. Evidence was introduced to show that Brady had been performing illegal abortions although he claimed to be a bartender by occupation.

Medical Conference—The North Central Medical Conference met at the Hotel St Paul, St Paul, December 10, under the presidency of Dr Leonard W Larson, Bismarck, N D, who discussed responsibility of medicine in planning for postwar medical services. Dr L Fernald Foster Bay City Mich, secretary, Michigan State Medical Society talked on prepaid medical service. Other speakers on the program included:

Dr Raymond G Arveson Frederic Wis A Wisconsin Committee Takes a Trip
Dr Alfred W Adson Rochester Council on Medical Service and Public Relations of the American Medical Association
Dr Joseph W Lawrence Washington D C My First Six Months in Washington
Mr Charles H Crownhart Madison Wis Shall State Associations Develop Committees on Medical Service and Public Relations?

NEW JERSEY

State Society Acquires New Home—The Medical Society of New Jersey has purchased a fifteen room house at a cost of \$30,000 at 315 West State Street, Trenton, to serve as its headquarters. Facilities are provided for the executive and

New home of state society

editorial offices as well as six meeting rooms for groups of 25 and one large assembly hall for a group of 150. The house is built of concrete with a green tile roof. The grounds are completely landscaped, offering ample accommodations for parking cars as well as a seven car garage. The entire property is 90 by 420 feet. The interior is now being redecorated, and the society hopes to occupy it by Christmas.

NEW YORK

Fellowship in Public Health—The Mary Pemberton Nourse Fellowship in public health is open for award by Vassar College Poughkeepsie, April 1. The fellowship amounting to \$2,500, is offered to a woman college or university graduate for original and outstanding work in public health at any approved institution. The money is intended to enable her to spend a year in study, in the carrying forward of an original project or in writing on the subject. Candidates should submit their application not later than March 1. The award will be made by the Vassar College Committee on Graduate Study on the nomination of an advisory committee of three selected by the college, one representing public health interests, a physician and an expert in public health. Application blanks should be secured from and returned to the president's office Vassar College Poughkeepsie.

New York City

Treatment of Mental Disorders in Children—A feature of the proposed four million dollar postwar expansion program at Creedmoor State Hospital is an expenditure of \$300,000 to create a children's division for the exclusive treatment of mental disorders in young persons.

Remington Medal Presented—The Remington Honor Medal was presented to Dr Harvey Evert Kendig dean of the Temple University School of Pharmacy, Philadelphia at a dinner of the New York Branch of the American Pharmaceutical Association at the annual meeting December 12 (THE JOURNAL, June 24, p 589)

Personal—Mr Bernard S. Coleman, S.B., who for ten years has been secretary of the tuberculosis committee of the New York Tuberculosis and Health Association, has been appointed director of the council of National Jewish Tuberculosis Institutions, with headquarters in Denver, effective January 2.—Drs Thomas A. McGoldrick, formerly president of the Medical Society of the State of New York, and Thomas M. Brennan, both of Brooklyn, have recently been made Knights of St. Gregory the Great by Pope Pius XII for services to their faith and their charitable works in the diocese.—Dr Emanuel W. Lipschutz, Brooklyn, has recently been appointed adjunct professor of gastroenterology at the New York Polyclinic Medical School and Hospital

Trauma and Cardiac Disabilities—The role of trauma in the causation of cardiac disabilities is the theme of a new program sponsored by the New York Cardiological Society which will be carried out as a continuing series of investigations and reports on clinical statistics, experimental investigation, pathology and medicolegal aspects. The object of the new project is to study all angles of the relationship between trauma and heart disease and to formulate, on the basis of the widest investigation possible, a reasonable code for the guidance of expert opinion. The project grew out of a suggestion by Dr Raphael Lewy, chief medical consultant of the workmen's compensation bureau New York State Department of Labor, now retiring after more than thirty years of service, who said that expert opinions have shown such wide variance that it is of paramount importance for some dispassionate and competent body to examine all evidence in the literature and conduct such investigations as will produce a set of reasonable criteria that will have authority and general acceptance. Various grants and funds from the society's treasury will be used to finance the work. On January 24 an introductory meeting will be held at the New York Academy of Medicine to which interested organizations, practicing physicians and officials are invited. Information may be obtained from the secretary of the New York Cardiological Society, Dr Philip Reichert 480 Park Avenue, New York 22

OHIO

Special Society Election—Dr Clarence E. Hufford Cleveland, is the new president of the Ohio State Radiology Society. Dr Harold G. Reineke, Cincinnati, is vice president and Dr Henry Snow, Dayton, secretary-treasurer.

State Society Organizes Insurance Company—The Ohio State Medical Association announced on November 16 that it was organizing a "stock medical expense insurance company" to be owned by its members, which would offer policies covering doctor's bills and supplementing established group hospitalization programs. Newspaper reports indicated that the association would not operate the company but was merely the organizing agency. When the company is incorporated and ready for operation it will be administered under the guidance of members of the medical profession who have become stockholders and incorporators.

Charles Doan Appointed Dean of State University—Dr Charles A. Doan, since 1936 chairman of the department of medicine at the Ohio State University College of Medicine Columbus, has been appointed dean of the medical school effective at once. Dr Hardy A. Kemp, who took a leave of absence in 1942 to enter military service, has been appointed professor of public health and hygiene, to become effective on his return to the campus. Dr Leslie L. Bigelow served as acting dean of the medical school until his death, Jan 15 1943. Since then Rollo C. Baker, Ph.D., has been acting dean. He will continue as professor of anatomy. Dr Doan graduated at Johns Hopkins University School of Medicine, Baltimore in 1923. He joined the staff at Ohio state in 1930 as professor of medicine and director of the department of medical and surgical research. In 1936 his title was changed to chairman of the department of medicine.

TEXAS

Proposed Merger of City and County Health Departments—The Dallas County Medical Society has approved a recommendation to consolidate the city and county health departments which if adopted by the city council and county commissioners court and subsequent legislation, would provide that the merged unit would be housed in enlarged headquarters at Parkland Hospital, jointly operated by the city and county.

Physicians Cooperate in Hospital Unit—Physicians in Dallas are cooperating in defraying the expenses of one complete unit of the Truett Memorial Building at Baylor University Hospital. The unit will be identified by a plaque bearing the name of the Dallas County Medical Society as the donor and \$50,000 will be raised from members of the society to underwrite the cost of the unit. According to the *Texas State Journal of Medicine* this action was part of a campaign to raise \$1,200,000 for the memorial building and new quarters for the Baylor University School of Nursing and College of Dentistry.

WISCONSIN

Memorial to Physician—On December 17 an electric organ will be dedicated at Wisconsin Memorial Park Cemetery in memory of the late Dr. Christopher G. Johnson, Chicago and Milwaukee. The organ is the gift of Mrs. Johnson and the ceremonies will take place in the park's Memorial Church, Milwaukee.

GENERAL

Prize for Work on Glaucoma—A prize of \$500 for the most valuable original paper adding to existing knowledge about the diagnosis of early glaucoma or the medical treatment of noncongestive glaucoma is being offered by the National Society for the Prevention of Blindness, 1790 Broadway New York 19. This award will take the place of two separate prizes of \$250 each which had been announced in THE JOURNAL, Dec 12, 1942, page 1238, and Aug 21, 1943, page 1197. Papers may be presented by any practicing ophthalmologist of the Western Hemisphere and may be written in English, French, German, Italian, Spanish or Portuguese. Those written in any of the last four languages should be accompanied by a summary in English.

Child Care Pamphlets—The bureau of child hygiene of the New York City Department of Health issues a series of pamphlets on child care, one group designed for the professional staff concerned with the care of children, the other for parents. Many of the pamphlets concern eating habits. For these the demand has been exceedingly great, so that more than 300,000 of these have been issued. The pamphlets which are purchasable at cost directly from the New York City Committee on Mental Hygiene, 105 East Twenty-Second Street New York City, include:

Eating Problems of Children
If Your Child Does Not Eat Well
Children Like to Eat
Children's Eating Habits
What Should We Expect of Our Children?

Health Security in Postwar America—The second wartime conference on labor health security was held at the Hotel McAlpin, New York, December 8. The theme of the general session was "Health Security in Postwar America" with the following speakers:

Mr. Eugene P. Connolly, secretary, New York County, American Labor Party
Miss Bertha C. Reynolds, director, Personal Service Department, National Maritime Union of America C. I. O.
Representative Adam Clayton Powell Jr.
Miss Helen Hutton, field secretary, Fort Greene Industrial Health Committee
Mr. Winslow Carlton, temporary secretary, Health Insurance Plan of Greater New York
Mr. George F. Addes, Detroit international secretary, treasurer, United Automobile Workers of America C. I. O.
Alfred J. Asgis, Ph.D., chairman, Health Council, American Labor Party

A series of panel discussions on postwar health and relocation of health personnel made up the second session.

Contact Lens Society Formed—The Society for the Advancement of Contact Lens Research was organized at a meeting in New York, November 18. Active members will consist of ophthalmologists, optometrists, dispensing opticians, contact lens technicians and manufacturers of contact lenses while associate membership will be available to persons who are interested in the advancement of contact lenses and in their development. The board of directors is to consist of fifteen members, three to be ophthalmologists, three optometrists, three opticians, three contact lens technicians and three contact lens manufacturers. The society will aim to improve and promote research in and development of contact lenses, to establish a foundation for research in any or all phases of the contact lens field and to instill mutual understanding and cooperation among all persons interested in contact lenses by disseminating authoritative information. Members of the organizing committee were Philip L. Salvatori, New York, Ewing Adams, O.D., Detroit, Albert L. Anderson, Minneapolis, Phil E. Dempsey, Toledo, Ohio, Dr. Abraham Allan Rossby, New York, and Gertrud Salvatori, New York.

LATIN AMERICA

Health Activities in Latin America—*New Journal*—*Arquivos Brasileiros de Nutricao* a monthly journal, recently made its appearance. It is the organ of the National Department of Nutrition in Brazil, which works in collaboration with the Nutrition Foundation of New York. Dr Josue de Castro, Rua Ararajo Porto Alegre Rio de Janeiro, Brazil is the editor. The first three issues contain a section of original articles, editorials, literature on nutrition and news.

Society News—The Medical Association of the Isthmus Canal Zone was addressed on October 17 at the Margarita Hospital among others by Drs Merrill H. Judd, Cristobal, C. Z. and James P. Wallace Cleveland, on "Treatment of Burns." Oscar Fannenbaum, New York, "Diagnosis of Cardiovascular Syphilis" and Oakley K. Park St. Louis, "Penicillin or Chemotherapy."—Dr Gregoria Arroz Alfaro, Buenos Aires was recently appointed president of the Instituto Internacional Americano de Proteccion a la Infancia, and Dr Victor Icardo y Araya, Montevideo, Uruguay, secretary and director of the department of health.

Bust of William Harvey Unveiled—On October 30 at a special meeting of the faculty of medicine of the National Autonomous University of Mexico, a bronze bust of William Harvey the discoverer of the circulation of the blood was unveiled. It is the work of Dr J. G. Martin del Campo. Dr Alfonso Caso, dean of the university, presided and speakers included Mr Charles H. Bateman the ambassador of England in Mexico, and Dr J. J. Izquierdo.

Personal—Two Panamanian physicians are among the Latin America students who arrived in London early in October to study under the sponsorship of the British Council. Dr J. Bianchi will undertake a general study of gastroenterology, while Dr J. Gonzalez will be attached to the oral surgery section of East Grinstead Hospital.—Drs Gabriel Gomez Del Rio professor of pediatrics at the University of Havana and director of Children's Hospital and Dr Aurelio Iturbe G. De La Solana minister of public health and chief of the medical division of the Linley Institute spent several weeks' study on poliomyelitis at the University of Chicago recently. The two physicians have been named chief consultants in Cuba's new poliomyelitis hospital which was to be opened in Cuba some time in November it is reported.—Dr Rafael Angel Calderon Guardia, formerly president of Costa Rica recently visited Mexico City on his way to New York City, where he will study with Dr George T. Pack. In a report to the press Dr Calderon Guardia is reported to have said that his decision to pursue cancer research was inspired by the death of his father, also a physician from cancer.—Dr Marjorie L. Warner, a 1944 graduate of Ohio State University College of Medicine, Columbus is said to be the first American woman to serve as an intern at Santa Tomas Hospital, Panama City.—Dr Wayne Gilder was recently presented with \$250 worth of war bonds in recognition of his more than twenty years service at Colon Hospital Cristobal, C. Z. where he is now serving as district physician.

First Tuberculosis Sanatorium in Haiti—A 100 bed hospital, financed by public subscription was recently completed at Port au Prince, the result of efforts of the National Antituberculosis League of Haiti, founded in July 1942 to help the government combat tuberculosis. The sanatorium is said to be the first of its kind in Haiti. In describing the new project the *Bulletin* of the National Tuberculosis Association states that since death registration in Haiti is inadequate the only reliable indication of the relative importance of various diseases lies in the records of government hospitals where tuberculosis is the principal cause of death and further that the disease has shown a well defined tendency to increase from 1918 to 1941. Haiti has a population of three and one half million on a land surface of 28,000 square kilometers half of which consists of lofty mountains. While no accurate figure can be given on the morbidity of the disease the first figures compiled since April 1941 show the following information for positive skin reactions to tuberculin tests:

from 0 to 1 year	37.7 per cent
from 1 to 2 years	50 per cent
from 3 to 12 years	60 per cent
from 12 to 18 years	85 per cent
among students	80 to 85 per cent
among adults of all ages	85 to 90 per cent

Leprosy Conference—The International Leprosy Association and the Pan American Sanitary Bureau are planning a second Pan American Leprosy Conference for Rio de Janeiro sometime in 1945. Dr. Pedro L. Balina, Buenos Aires, is the chairman and H. C. de Souza-Arroyo the vice chairman of the western section of the International Leprosy Association. A feature

of the conference will be the presentation of three prizes for articles on leprosy, created by the National Academy of Medicine of Rio de Janeiro. First prize, of about \$500, will be given for the best work on etiology and pathogenesis of leprosy. Second and third prizes, of about \$250, will be given for articles on practical results of treatment of leprosy and history and epidemiology of leprosy in Brazil.

FOREIGN

Proposed Chair of Dermatology—A gift of £70,000 has been made to the University of Edinburgh by Sir Robert McVitie Grant to establish a chair of dermatology which it is reported in *Science*, will be the first of its kind to be created in Great Britain.

All Negro Mission for Health Program—At the request of the Liberian government an all Negro mission of eleven American physicians, engineers, entomologists and nurses has been created by the U. S. Public Health Service in cooperation with the state and war departments at the direction of President Roosevelt to develop a five year health and sanitation program in Liberia. Members of the group include Dr. John Baldwin West, head of the mission and senior surgeon in the U. S. Public Health Service; Granville W. Woodson, sanitary engineer, and John P. Davies Jr., maintenance superintendent. The mission will be expected to do whatever it can to bring communicable diseases in Liberia under control, to protect as far as possible the military personnel and transients from the United States and other Allied nations in Liberia against such diseases and to reduce the chances of their transmission to the United States. The various aspects of the mission's work will be financed by public and private agencies, the major portion to be borne by the public health service. The division of cultural cooperation of the Department of State is contributing funds to be used for the improvement of nursing education, a program that will be under the jurisdiction of the mission. Fellowships for the medical training of Liberians in this country will be provided by the Rockefeller Foundation. The mission's work will be similar to the extracantonment activity now carried on by the public health service in cooperation with state and local health departments in the vicinity of military establishments in the United States and to the work of the public health service venereal disease control mission, which was sent to Trinidad with the permission of the British government, and to the work of American missions in controlling malaria along the Burma Road and in aiding the Chinese government in controlling that disease and improving sanitary conditions along the railroad paralleling the Burma Road. The Liberian health mission will apply malaria control procedures in Monrovia, Kakata, Roberts Field and Fish Lake and the country surrounding those localities. In addition to draining and filling, it will carry on spraying and house spraying. In the water borne disease field the mission will check existing wells and other sources of water supply, condemn polluted sources and drill temporary wells where need for them is established. A survey will be made to determine the need for a temporary filtration plant at Monrovia to protect transients and provide ships with water. The sewage disposal methods now in use will be studied with a view to their improvement, and a program of food inspection will be inaugurated to form the basis of recommendations to the government of Liberia for national legislation covering the sale of foodstuffs. The mission's work will involve in addition to the draining and filling of swampy areas the utilization of other methods of controlling aquatic forms of disease transmitting agents. It will also have control of water supply and sewage disposal. The mission will be expected to assist the Liberian government in the development of a broader public health service including the training of a director, the establishment of divisions of communicable disease control, malaria control, venereal disease control, vital statistics and other divisions essential to the needs of the republic.

CORRECTION

American Public Health Association Health Insurance Declaration—In the editorial with this title on page 434 of *THE JOURNAL*, October 14 it was stated that 'of the 7,493 members of the American Public Health Association 1,571 are Fellows'. *THE JOURNAL* is now informed by the American Public Health Association that these figures were intended to be mutually exclusive that is, 7,493 members plus 1,571 Fellows, a total of 9,064.

Nov 11, 1944

International Unit of Penicillin

A conference convened in London by the Health Section of the League of Nations has agreed on the standardization of penicillin. Sir Henry Dale, president of the Royal Society, presided at the conference. The delegates were as follows: Australia, Major J L Bazeley (Commonwealth Serum Laboratories), Canada, Dr G D W Cameron (chief, Laboratory of Hygiene, Department of Pensions and National Health, Ottawa), France, Dr J Trefouel (director of the Pasteur Institute), United Kingdom, Dr C R Harington (National Institute of Medical Research) and Dr J W Trevan (Wellcome Physiological Research Laboratories), United States, Dr R D Coghill (Northern Region Research Laboratory, Peoria, Ill), Dr R P Herwick (chief of the Drug Division of the Food and Drug Administration) and Dr M V Veldee (chief, Division of Biologics Control, U S Public Health Service). Sir Alexander Fleming, the discoverer of penicillin, and N G Heatley attended as advisers. The international unit agreed on was 'the specific penicillin activity contained in 0.6 microgram of the international standard,' but particulars of the standard have not yet been announced.

Casualties of the Bombardment of England from the French Coast

The strip of England nearest France contains the pleasant seaside resorts of Dover, Folkestone, Deal, Ramsgate and the neighboring villages. They are in no sense military targets, but for four years they have been bombarded by the Germans from the French coast as part of 'total war.' This locality has therefore earned the name of "Hellfire Corner." When the mayor of Dover recently announced the receipt of official information that all long range guns on the other side of the English Channel had been captured, the people were quick to celebrate the occasion by gathering in the streets, shouting, dancing and singing. The casualties of the four year bombardment can now be given. The total number of shells recorded, which is not quite complete, is 2,565. These killed 157 persons and injured 671, though the inhabitants lived largely in shelters. In addition, 163 persons were killed and 611 injured by bombs. The worst bombardment of Dover was on Sept 26, 1940, when in five hours 63 shells fell, nearly 50 in one area. A hostel was hit and 49 persons were killed.

British Share Their Rations with the Greeks

The Germans deliberately produced a famine in Greece. In addition to their usual barbarities they seized the whole supply of olive oil, of which Greece is the principal producer in Europe, and also the fruits of the Greek islands. The result was that a large proportion of the population perished from starvation. Immediately on entering Greece the British brought food supplies, but transport is a great difficulty. Greece now obtains 130,000 tons of supplies a month, made up of 50,000 tons of wheat, 10,000 tons of other food and 70,000 tons of clothes and medicines.

Research on Human and Animal Trypanosomiasis

The secretary of state for the colonies has appointed a tsetse fly and trypanosomiasis committee to consider and advise on the coordination of action, including research directed against human and animal trypanosomiasis and in particular against the tsetse fly as the chief vector. The committee, on which the Dominions Office and the Sudan government are represented will report from time to time to the secretary of state. On all

matters affecting research its recommendations will be referred to the Colonial Research Committee for comment and advice before submission. The committee includes Prof P A Buxton, London School of Tropical Medicine, Dr H Lyndhurst Duke, lately director of the Human Trypanosomiasis Institute in Uganda and chairman of the League of Nations Sleeping Sickness Committee. Prof I M Heilbron, Imperial College of Science, Dr E M Lourie, Liverpool School of Tropical Medicine, Dr S A Neave, director of the Imperial Institute of Entomology, Dr A H G Smart, medical adviser to the secretary of state for the colonies, Mr John Smith, adviser on animal health to the secretary of state for the colonies, and Dr H A Tempany agricultural adviser to the secretary of state for the colonies.

Skin Cover for War Wounds and Burns

The War Office has issued to all medical officers a memorandum on skin cover for wounds and burns. This begins by pointing out that there is little scope for primary closure of wounds caused by missiles because (1) infection is deeply introduced, (2) the time lag between injury and primary operation is usually greater than in industrial injuries and (3) it is seldom possible for the wounded man to remain at the surgical center which first deals with his wound. Hence most medical directorates completely ban the procedure. But this creates an urgent secondary problem: finding the best methods, when the danger period is over, to obtain early closure. It is recommended that consulting surgeons should bring to the notice of all surgeons in their command the value of delayed primary suture, secondary suture and simple skin grafting. Delayed or secondary suture should be considered (1) when the bacteriologic state of the wound is under control (sterility cannot be expected), (2) when the loss of tissue, particularly skin, is small and (3) when the deeper tissues, especially muscle, can be brought together without undue tension. A common cause of failure is suture of the skin under excessive tension.

Skin cover by free grafting should be the method of choice when the loss of tissue makes secondary suture impossible. All open granulating wounds should be closed or grafted before that deep unabsorbable fibrous base develops which will neither heal nor accept a graft but which will later require a complicated plastic operation. Spaced postage stamp razor grafts laid on tulle gras sheets are especially useful when sepsis is anticipated. This procedure is recommended for all surgeons. But experienced general surgeons should employ a "direct flap" in cases of avulsion of the skin in such regions as the hand, wrist or forearm laying bare or damaging tendons, nerves or joints. The damaged area should be covered by an immediate abdominal flap. The "grenade hand" is an example. Injuries of the lower leg, ankle and foot, if bone and tendons are exposed, should be transferred to a plastic surgery center. This also holds for the knee and popliteal regions if the defect is large.

Preparation for Medical Demobilization

At the request of the minister of health a subcommittee of the Central Medical War Committee known as the Demobilization Committee was appointed to advise on the release of medical officers after the war. The government had announced that the main considerations in determining priority of release would be age and length of service. The task of the committee was to determine how best under this general plan to combine justice to the serving doctors and satisfaction of the more urgent needs of civilian practice. The result of its recommendations is the following plan adopted by the government. General demobilization must await the total defeat of the Axis. All that is now contemplated is reallocation of manpower between the armed forces and civilian work when Germany has been defeated while Japan remains at war. As there can be no break in the war effort, military requirements will override all other considerations. Compulsory recruitment for the armed forces will

be continued. But it will be possible to bring relief to the men who have served for long periods and through continued recruitment to enable them to return home. There will be two methods of selection. A larger group will be selected for release according to age and length of service, a smaller group will consist of men required for urgent reconstruction work at home. These will include a limited number of men with special qualifications, for whose transfer application must be made through government departments. No man will be released if his retention is considered necessary on military grounds. In the former class there will be a special priority group for men over 50, who will be released before others if they wish. Otherwise the criterion will be a combination of age and length of war service on the basis that two months of service equals one additional year of age.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO Nov. 20 1944

A Meeting of Obstetricians and Gynecologists

Jointly organized by the Brazilian Society of Obstetrics and Gynecology and by the São Paulo State Medical Association a large meeting of practitioners of these medical specialties from the cities of Rio de Janeiro and São Paulo, the two most important medical centers of the country, has just been held in this city. Among the leading figures present at the meeting were Drs. Arnaldo de Moraes, J. Rodrigues Lima, Ary Novis, Goulart de Andrade, Paulo Barata, Motta Maia and Mario Pardal from Rio de Janeiro, and Drs. Ayres Netto, Altino Antunes, Escobar Pires, Cyro Camargo, Arruda Sampaio, Jose Gallucci, Wolff Netto and A. Guidi from São Paulo. The more important subjects discussed at the meeting were the treatment of uterine prolapse, arrhenoblastoma, hypernephroid tumor of the ovary, anemias of pregnancy, grading the malignancy in cancer of the uterine cervix, early diagnosis of cancer of the uterine cervix, neonatal mortality, x-ray visualization of the placenta, uterine cancer and pregnancy, surgical treatment of uterine myoma, indication of the different kinds of anesthesia in gynecology and gigantic tumors of the ovary.

At the close of the meeting Dr. A. Oliveira Lima, commissioner of health for the Federal District (Rio de Janeiro) addressed the obstetricians and gynecologists to point out the present situation in the administration of maternity care in the largest city of Brazil. He began by emphasizing that in this city an average of almost 50 per cent of the maternal deaths are due to puerperal infection, more than 20 per cent to toxemia and more than 10 per cent to hemorrhage. These figures define the large task that the health organization of the city has to face, particularly because the number of hospital beds for maternity is clearly insufficient. Out of a total of 41,768 births registered during the year 1943, only 14,606 deliveries were attended by physicians in hospitals. There are 207 beds for maternity cases in the eight municipal hospitals (an average of 25.9 beds per hospital) while 6,480 pregnant women were attended during the year 1943, an average of 31.3 deliveries per bed during the year, which corresponds to an average of 11.7 days per bed per case. The only hospital entirely devoted to maternity cases in Rio de Janeiro is the Pro-Matris Hospital, which is a private institution. But the city administration has completed plans to erect a lying-in hospital with 400 beds, the building of which is about to begin.

Sixth Pan American Congress of Tuberculosis

The sixth Pan American Congress of Tuberculosis will be held at Havana, Cuba, in January 1945 to discuss three main subjects: BCG vaccine in the control of tuberculosis, clinical forms of incipient tuberculosis and the systematic plan of treatment of cavernous tuberculosis. The Brazilian committee for the organization of the congress has chosen Drs. Arlindo de Assis, Manoel de Abreu and A. MacDowell to present spe-

cial reports on these subjects. Drs. Jose Rosemberg, Jayme S. Neves, Reginaldo Fernandes, Alberto Renzo A. Ibiapina, Aresky Amorim and Hugo Pinheiro Guimarães will also present papers on the same topics.

Malaria in the State of São Paulo

The Service of Malaria Control of the São Paulo State Health Department recently published an important volume with tables, diagrams and half-tones to show its work in the last few years. The organization of the service includes several divisions: the Division of Treatment and Education, which has about fifteen fixed stations located in the malarial districts and a few movable stations; the Division of Statistics and Epidemiology; the Division of Control, which is in charge of all the work of spraying houses, oiling and dusting ponds and marshes, draining seepage water and collecting blood samples; and the Division of Laboratory, with such tasks as examining blood samples and classifying mosquitoes. An important part of the service is the Malaria Experiment Station at Guarujá, where many valuable studies have been made. The tables and graphs show that the death rate from malaria in all the state of São Paulo varied from 10.53 per hundred thousand of population in 1930 to 39.00 per hundred thousand in 1938, the minimum rate having been 8.25 in 1938. The number of cases reported varied from 3,291 in 1933 to 181,398 in 1941, when there was a serious outbreak. The lowlands of the Atlantic border which represent only 5 per cent of the area of the state, had 40.64 per cent of the cases during the 1941 malarial season.

Brief Items

Dr. Jorge de Moraes Grey, a practicing surgeon at Rio de Janeiro, has been elected to membership of the National Academy of Medicine.

Dr. Florencio de Abreu, director of the Central Army Hospital of Rio de Janeiro, has been elected president of the Brazilian Academy of Military Medicine.

A special course in cancerology is being given at the St. Francisco de Assis Hospital at Rio de Janeiro. Drs. Doellinger da Graça, Vital Fontenelle, Moraes Grey, Augusto Paulino and Rabello Filho e Armando Aguinaga are teaching this course.

A recent cablegram from Buenos Aires has announced that Dr. Aloysio de Castro, professor emeritus of medicine at the University of Rio de Janeiro and president of the National Academy of Medicine, has been honored as a guest at the Athenaeum of History of Medicine of Argentina.

Dr. Eugene Kisch of the Hospital for Joint Diseases of Far Rockaway, New York, is spending several days at Rio de Janeiro as a guest of the Ataulfo de Paiva Foundation, an organization interested in the campaign against tuberculosis in this city. He has lectured at the National Academy of Medicine and at the Brazilian Tuberculosis Association on the treatment of osteoarticular tuberculosis.

Dr. Ovidio Meira, director of the St. Zacarias Children's Hospital of Rio de Janeiro, died at the age of 64. He was one of the leading orthopedists of the country.

Marriages

CHARLES L. WILLIAMS JR., P. A. S. U. S. Public Health Service, Ann Arbor, Mich., to Miss Alice Griesemer of Reading, Pa., October 14.

ROBERT W. MACKIE of Rockville Centre, N. Y., to Miss Lillie McWhinney Smith of Lawrence in South Mills, N. C., October 14.

VERNON HUTTON JR., Nashville, Tenn., to Miss Margaret Helen Turner in Hattiesburg, Miss., October 15.

E. DAVID BLECHMAN, Newport News, Va., to Miss Carolyn Hess of New York, November 30.

SIDNEY GOVER to Miss Ray Katz, both of New York, November 11.

Deaths

Benjamin F Bailey ♂ Lincoln, Neb., Hahnemann Medical College of Philadelphia, 1881, member, House of Delegates, American Medical Association, 1930-1937, past president of the Nebraska State Medical Association, Lancaster County Medical Society, state board of health, American Institute of Homeopathy, Nebraska State Homeopathic Medical Society, the American Interprofessional Institute, Northwest Regional Conference Council of Social Agencies and the Lincoln board of education, interstate supervisor of education of the draft, U S P H S, in the last months of World War I for Nebraska, Iowa, Wisconsin, Minnesota, North Dakota and South Dakota, director of the First National Bank and Union Loan and Savings Association, past president of the Lincoln and Nebraska Society, Sons of the American Revolution and the Lincoln Chamber of Commerce, for twenty years president of the Lincoln and Lancaster County American Red Cross, formerly trustee of the Y M C A, president and chief of staff, Green Gables, Dr Benjamin F Bailey Sanatorium, which he established in 1901, joint author of "Present Status of Pediatrics", served as chairman of the committee on journal and publication, Nebraska State Medical Association, died October 31, aged 84 of cerebral hemorrhage.

Benjamin Franklin Buzby ♂ Narberth, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1914, formerly instructor in surgery at his alma mater, specialist certified by the American Board of Orthopaedic Surgery, Inc., past president of the Camden County Medical Society, member of the American Academy of Orthopaedic Surgeons and Philadelphia Academy of Surgery, past president of the Philadelphia Orthopedic Club, fellow of the American College of Surgeons, served overseas as a captain in the medical corps of the U S Army during World War I, on the courtesy staffs of the Bryn Mawr Hospital, Bryn Mawr, Pa., and the Chestnut Hill Hospital, Germantown, Pa., consulting orthopedist, Underwood Hospital, Woodbury, N J, and Camden County institutions Lakeland, N J, chief of orthopedic service at the Burlington County Hospital, Mount Holly, N J, Germantown Dispensary and Hospital, Philadelphia, and the Cooper Hospital, Camden, N J, where he died October 22, aged 53, of acute lymphatic leukemia.

Ralph Clinton Cupler, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, also a pharmacist, fellow of the American College of Surgeons, for many years a member of the Chicago Surgical Society, life member of the Surgical Society of Rochester, Minn., captain in the medical corps of the U S Army during World War I, formerly demonstrator of operative surgery and anatomy at the Chicago Polyclinic, formerly professor of clinical surgery at the Bennett Medical College and the Chicago College of Medicine and Surgery, surgeon at St Anthony's Hospital from 1905 to 1933 and in 1903 gynecologist, in 1903 member of the associate staff at Cook County Hospital, surgeon for the Illinois Central Railroad, died in Wilmette, Ill., October 24, aged 65, of coronary occlusion.

Harold Eliphalet Hoyt, Long Island City, N Y, Albany Medical College, Albany, 1904, member of the American Medical Association and the American Psychiatric Association, served on the faculty of the New York Homeopathic Medical School, veteran of the Spanish-American War, captain in the medical corps of the U S Army during World War I, formerly physician in charge of Fitch's Home for Soldiers, Noroton Heights, Conn., served as resident psychiatrist at Blythwood, Greenwich, Conn., on the staff of West Hill Sanitarium, New York, and as assistant attending and associate attending neurologist at the Metropolitan Hospital, New York, a member of the staff of the River Crest Sanitarium, Astoria, since 1933 and physician in charge since 1935, died in St John's Long Island City Hospital October 12, aged 66 of carcinoma.

Sterling B Taylor, Columbus, Ohio, Starling Medical College, Columbus, 1890, member of the American Medical Association, fellow of the American College of Surgeons, in 1939 retired as local surgeon for the New York Central Railroad, in 1934 president of the American Association of Railway Surgeons, lecturer on anatomy at the Ohio Medical University from 1892 to 1899, Starling Medical College from 1903 to 1906 and Starling-Ohio Medical College 1907-1908, served as major in the medical corps of the Ohio National Guard, on the staff of the Grant Hospital, died in St Petersburg, Fla., September 21, aged 75 of coronary heart disease.

Antonio Lagorio, Chicago, Rush Medical College, Chicago, 1879, founder and director of the Pasteur Institute, member

and president of the board of directors of the Chicago Public Library from 1906 to 1917, served as trustee of the House of Correction, received the Italian Cross of Chevalier and the silver medal of the Italian Red Cross and in 1922 the Order of the Grand Knight of the Crown of Italy, received the honorary LL.D. from St Ignatius College 1907, said to be the first to bring the Pasteur treatment to the United States fifty-five years ago, died in the Columbus Hospital November 26, aged 87 of diabetes mellitus.

George Sloan Dixon, New York, Bellevue Hospital Medical College, New York, 1885, member of the American Medical Association, the American Academy of Ophthalmology and Otolaryngology and the American College of Radiology, specialist certified by the American Board of Radiology, formerly instructor of otology at the Columbia University College of Physicians and Surgeons and professor of roentgenology at the School of Ophthalmology and Otology, New York, president of the New York Roentgen Society in 1924, on the staff of the New York Eye and Ear Infirmary from 1893 to 1935, died October 9, aged 91, of carcinoma of the throat.

Charles Atsatt Sparrow ♂ Worcester, Mass., Harvard Medical School, Boston, 1910, member of the American Academy of Pediatrics and the New England Pediatric Society, past president of the Worcester District Medical Society and counselor of the Massachusetts Medical Society, chief, pediatric service, Memorial Hospital, Worcester, and consultant to the Milford Hospital, Milford, chief medical officer of Civilian Defense, Worcester District, an associate editor of the *Worcester Medical News*, died September 20, aged 60, of pulmonary embolism and coronary occlusion.

Eugene Hertel Vachon, Hartford, Conn., University of Montreal Faculty of Medicine, Montreal, Que., Canada, 1941, served internships at Hotel-Dieu de St Joseph, Montreal, St Jean de Dieu Hospital, Gamelin, Que., and the Hospital St Justine, Montreal, Que., served a residency in medicine at the Middlesex Hospital, Middletown, and at the State Veterans Hospital in Rocky Hill, formerly in charge of anesthesia at the Davis Memorial Hospital, Elkins W Va., on the staff of St Francis Hospital, where he died September 25, aged 35, of coronary occlusion.

Charles Baker Adams, New York, Columbia University College of Physicians and Surgeons, New York, 1900, served on the staffs of the New York, Bellevue and Post-Graduate hospitals, died in the Columbus Hospital October 18, aged 70.

Jesse Curtis Akins, Forreston, Ill., Barnes Medical College, St Louis, 1899, member of the American Medical Association, on the staffs of the Deaconess and St Francis hospitals, Freeport, for many years coroner of Ogle County, president of the White Oak Cemetery Association, died October 4, aged 75, of cardiac decompensation and uremia.

Sidney Watson Badcon, Ogden, Utah, Northwestern University Medical School, Chicago, 1912, member of the American Medical Association, served an internship at the Thomas D. Dee Memorial Hospital, where he had been on the staff and for two years president of the board, county physician, died in Samaritan Hospital, Denver, October 7, aged 73, of carcinoma of the prostate.

Vincent A Ball ♂ Tonawanda, N Y, University of Buffalo School of Medicine, 1921, died in the De Graff Memorial Hospital, North Tonawanda, October 11, aged 48, of coronary occlusion.

Abram James Barker ♂ Torrington, Conn., Bellevue Hospital Medical College, New York, 1897, past president of the Litchfield County Medical Society, member of the draft medical advisory board during World War I, surgeon for the American Brass Mill for many years, on the consulting staff of the Charlotte Hungerford Hospital, where he died October 2, aged 76 of coronary thrombosis and chronic valvular disease.

Lyman Guy Barton ♂ Plattsburg, N Y, Bellevue Hospital Medical College, New York, 1891, an Affiliate Fellow of the American Medical Association, fellow of the American College of Surgeons, devised Barton forceps, skull tongs and other instruments, on the staff of Champlain Valley and Physicians hospitals, died November 21, aged 78 of coronary occlusion.

Edward I Brown, St Paul, Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1900, member of the American Medical Association, on the staff of the Bethesda Hospital, where he died October 8, aged 75, of cerebral hemorrhage.

Thomas David Brown, Ogdensburg, N Y, Bellevue Hospital Medical College, New York, 1898, died October 6, aged 71, of coronary occlusion.

Femulus S Buckland ♂ Baraga, Mich., Fort Wayne College of Medicine Fort Wayne, Ind., 1892, formerly associated with the Indian Service and superintendent of the Mackinac School, formerly health officer of Baraga Village, on the staff of St Joseph's Hospital Hancock, the Buckland Athletic Field at Baraga High School bears his name in recognition of his many contributions to the community for many years chairman of the Baraga County Republican Committee, died October 13, aged 78

Elliot T Bush ♂ Elmira, N Y, University of Buffalo School of Medicine, 1903, past president of the Chemung County Medical Society, member of the American Urological Association, fellow of the American College of Surgeons, for many years honorary member of the Rotary Club, on the staffs of St Joseph's Hospital and the Arnot-Ogden Hospital, where he died October 12, aged 64

James Clyde Butler, Hutchinson, Kan., Tennessee Medical College Knoxville, 1894, member of the American Medical Association, formerly surgeon to the National Soldiers' Home in Tennessee, at one time associated with the Dykes Hospital in Stafford, served during World War I, died November 14, aged 73

Victor Warren Byrnes, Durant, Iowa, State University of Iowa College of Medicine, Iowa City 1897, past president of the Cedar County Medical Society, died October 16, aged 70, of coronary thrombosis

Andrew Roscoe Carrigan ♂ Manchester, Ohio, Kentucky School of Medicine, Louisville, 1903, served as a member of the Adams County Board of Health, died October 16, aged 64, of heart disease

Harry X Cline, Marion Ill., Washington University School of Medicine, St Louis, 1905, veteran of the Spanish American War and World War I, died October 15, aged 66, of coronary thrombosis

Edward W Cummins, Harrisburg, Ill., St Louis University School of Medicine, 1906, member of the American Medical Association, served twice as president of the Saline County Medical Society, president of the board of the Saline County Tuberculosis Society, for many years member of the city school board director of the First National Bank and physician for the Wasson Coal Company, formerly commissioner and city and county health officer, served during World War I, died October 5, aged 66, of lymphosarcoma

Thomas Ridley Currie ♂ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1894, on the staffs of St Christopher's and Northeastern hospitals, died October 10, aged 79, of ruptured aneurysm of the abdominal aorta and generalized arteriosclerosis

Oscar Eisinger ♂ Cleveland, Medizinische Fakultät der Universität Wien, Austria, 1915, a captain in the Austrian army during World War I, medical examiner for the induction board of Cleveland, World War II, on the staff of the Polyclinic Hospital, died October 4, aged 53, of coronary thrombosis

Omar F Elder, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1909, associate member of the Medical Association of Georgia, died October 25, aged 58 of coronary sclerosis

Marcus Samuel Fletcher ♂ Georgetown, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1898 on the staffs of the Lakeview and St Elizabeth hospitals in Danville, served during World War I, for many years a member of the school board died October 9, aged 75, of carcinoma

Clark Barrows Hatch ♂ Newark Ohio, Starling-Ohio Medical College Columbus, 1904, member of the American Academy of Ophthalmology and Otolaryngology, an examiner for the draft board during World War I, formerly city health officer past president of the Rotary Club and the Y M C A board of directors, on the staff of the Newark City Hospital, where he died October 20 aged 65, of acute pulmonary edema

Samuel Barth Hirschberg, Los Angeles, Detroit College of Medicine 1908, served as a captain in the medical corps of the U S Army during World War I, formerly director of the Letterman General Hospital San Francisco, superintendent of the Mount Zion Hospital, San Francisco, and the Chicago-Winfield Tuberculosis Sanitarium Winfield Ill and medical director of the Beth Moses Hospital Brooklyn, died October 5, aged 61, of carcinoma of the stomach

Leonard D Hoskins, Pineville, Ky, Hospital College of Medicine, Louisville 1903, member of the American Medical Association died in Knoxville, Tenn October 11 aged 71

George P Huddle, Stoutsville Ohio, Starling Medical College Columbus 1888 died in the Lancaster Municipal Hospital Lancaster October 20 aged 82

Carl Aaron Hyer ♂ Columbus, Ohio, Ohio State University College of Medicine, Columbus 1920, from 1924 to 1928 member of the teaching staff of the Ohio State University College of Medicine as an assistant in the department of medicine, for many years on the staff of the Mount Carmel Hospital, member of the local Rotary Club, died suddenly October 13, aged 52, of cerebral hemorrhage

Raymond Delos Jamieson ♂ Racine, Wis., Marquette University School of Medicine, Milwaukee, 1913, past president of the Racine County Medical Society, member of the executive staff at St Mary's Hospital, where he served as roentgenologist for seven years and had been on the staff at St Luke's Hospital, died October 7, aged 53, of heart disease

Jacob Kaufmann ♂ New York, Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1885, formerly professor of clinical medicine at the Columbia University College of Physicians and Surgeons, member and past president of the American Gastro Enterological Association, member of the American Association for the Advancement of Science, attending physician at the Lenox Hill Hospital from 1895 to 1925, when he became consultant, a position formerly held at the Beekman Hospital, died October 13, aged 84, of senility

Frederick Krauss ♂ Elkins Park, Pa., University of Pennsylvania Department of Medicine Philadelphia, 1893, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons on the staffs of St Christopher's and Episcopal hospitals, Philadelphia and the Abington Memorial Hospital, Abington, where he died October 9, aged 73

Richard Vance Lynch ♂ Clarksburg, W Va, Eclectic Medical College, Cincinnati, 1910, past president of the Harrison County Medical Society, at one time physician for the Hutchinson Coal Company at Erie, physician for the Grasselli Chemical Company, Spelter, died November 13, aged 60 of heart disease

John McCampbell, Morganton, N C, Baltimore Medical College, 1894, member of the American Medical Association and the American Psychiatric Association, chairman of the district medical board during World War I, retired in 1938 as superintendent of the State Hospital, a position he had held for many years, served as a member of the state eugenics board died in the Davis Hospital, Statesville, November 5, aged 76, of carcinoma of the head of the pancreas

Wallace Delos Russell, New Hartford, N Y, University of the City of New York Medical Department, New York 1886, member of the American Medical Association, died September 27, aged 86 of generalized arteriosclerosis and heart disease

Scott Ryerson ♂ Daggett, Calif., University of Buffalo School of Medicine, 1931, specialist certified by the American Board of Surgery, diplomate of the National Board of Medical Examiners, fellow of the American College of Surgeons, served as assistant in surgery at his alma mater, formerly on the staffs of the Buffalo General and the Edward J Meyer Memorial hospitals, died in Buffalo September 17, aged 35, of coronary thrombosis

John Raymond Sheehan, Milwaukee, Chicago College of Medicine and Surgery, 1915, served during World War I, died in the Milwaukee County Hospital, Wauwatosa, September 28, aged 54, of acute peritonitis and perforated duodenal ulcer

Arthur Edwin Shell ♂ Clinton, Ill., University of Illinois College of Medicine, Chicago, 1915, served during World War I in 1931 appointed district surgeon for the Illinois Terminal Railroad System and the Illinois Power and Light Corporation died in St James Hospital September 3, aged 55, of coronary thrombosis

Charles Reynolds Sheridan, Detroit, University of Maryland School of Medicine, Baltimore, 1907, member of the American Medical Association, served as health officer of Hamtramck on the staff of St Francis Hospital, died October 3, aged 58, of heart disease

John B Slicer, Rising Sun, Md., College of Physicians and Surgeons Baltimore, 1884, formerly county coroner died in the Union Hospital Elkton, September 8, aged 86, of carcinoma of the liver

Albert Godfrey Smith, Oskaloosa Kan., University Medical College of Kansas City, Mo, 1886 member of the American Medical Association, honorary member of the Shawnee County Medical Society, formerly mayor served on the staff of Christ's Hospital, Topeka, died September 25 aged 84 of coronary thrombosis

John Henry Smith ☉ Duke Center Pa University of Pittsburgh School of Medicine, 1909 died in St Francis Hospital, Olean, N Y, September 3 aged 63 of acute peritonitis following perforation of colonic diverticula

Matthew B Smith, Fenton, Mich Saginaw Valley Medical College, Saginaw, 1898, formerly on the staffs of the Hurley and St Joseph's hospitals, Flint, died September 27, aged 72, of heart disease

Wayne Lawson Snyder, Brookville, Pa, Jefferson Medical College of Philadelphia, 1905, member of the American Medical Association, fellow of the American College of Surgeons, served overseas during World War I, formerly on the staff of the Brookville Hospital, died September 23, aged 63, of coronary heart disease

Chester A Spittler ☉ Middletown, Ohio, Indiana Medical College, School of Medicine of Purdue University Indianapolis, 1907, served as city physician and health officer for many years on the staff of the Middletown Hospital died September 14, aged 66, of chondrosarcoma

Guy N Stonemetz, Fairfield, Ill St Louis Medical College, 1885, for many years a druggist died September 22, aged 81, of nephritis and senility

Homer O Strosnider Keokuk, Iowa, Keokuk Medical College, College of Physicians and Surgeons, Keokuk, 1905, member of the American Medical Association, died September 29, aged 61, of pernicious anemia

John Armstrong Sugg, McEwen, Tenn, University of Nashville Medical Department, 1900 died September 1, aged 71

Robert Elmer Summitt ☉ Gainesville Fla, Tulane University of Louisiana School of Medicine, New Orleans, 1926 served during World War I, member of the Alachua County Hospital staff and past president, died September 12, aged 51 of heart disease

John Nelson Swartz ☉ Detroit University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892 died September 27, aged 72, of congestive heart failure

Green Benjamin Taylor, Cameron Texas, Memphis (Tenn) Hospital Medical College 1900 past president and secretary of the Milam County Medical Society and president of the Central Texas District Medical Society formerly vice president of the State Medical Association of Texas, for many years local oculist for the Santa Fe and Southern Pacific railroads, died September 2, aged 69, of coronary occlusion

Alfred Teebor, Newark, N J, Medizinische Fakultät der Universität Wien Austria, 1914, died September 23, aged 54, of coronary thrombosis

Henson Foster Tomb, Johnstown Pa, Jefferson Medical College of Philadelphia 1887, member of the American Medical Association, school physician, member of the consulting staff of the Conemaugh Valley Memorial Hospital where he died September 15 aged 83, of carcinoma of the liver

Rufus Henry Tomlinson, McKinnon, Tenn Vanderbilt University School of Medicine Nashville 1893, died in the Clarksville Hospital, Clarksville, September 27 aged 76, of heart disease

J Frank Van Voorhis, Rockford Ill Bennett Medical College Chicago 1889, died in the Swedish American Hospital September 17, aged 79, of cerebral hemorrhage

George Van Voris Warner, Red Bank, N J, Albany Medical College Albany 1902, past president of the Monmouth County Medical Society, served as president of the Monmouth County Mosquito Extinction Commission, on the staffs of

the Dr E C Hazard Hospital, Long Branch, and the Royal Pines Hospital Pinewald, died October 9, aged 67

Lloyd Cyrus Warren ☉ Franklin, N Y, Baltimore Medical College, 1911, a first lieutenant in the medical corps of the U S Army during World War I, since 1940 medical examiner for the Selective Service Board at Walton served as school physician, health officer of the town of Franklin, and coroner of Delaware County, on the staffs of the Aurelia Osborn Fox Memorial Hospital Oneonta, and The Hospital Sidney, died September 14, aged 61, of coronary occlusion

Benjamin Weiner, Pittsburgh, University of Pittsburgh School of Medicine, 1909, served during World War I died August 9, aged 56, of carcinoma of the lung

Milton Madison Wells ☉ Fairland, Ind, Medical College of Indiana, Indianapolis, 1901, served during World War I, for many years Brandywine township trustee died in the W S Major Hospital, Shelbyville, October 12, aged 73

Frank Kemper Westfall, Prairie City Ill, the Hahnemann Medical College and Hospital, Chicago, 1903, at one time on the staff of the Phelps Hospital, Macomb, died September 16 aged 64

Edgar Allen Widber, Monroe Township N J University of Vermont College of Medicine Burlington, 1894, died September 28, aged 83 of arteriosclerotic heart disease

James Salmon Wilkinson, Philadelphia Medico-Chirurgical College of Philadelphia, 1906 on the courtesy staffs of the Germantown and Chestnut Hill hospitals died October 3 aged 61, of nephritis

Lucius Gould Wright, Chicago, John A Creighton Medical College Omaha, 1910, served during World War I, died September 23, aged 69, of atrophic cirrhosis of the liver

Herbert Leroy York, Melrose, Mass Harvard Medical School, Boston 1899, retired druggist died in the Corey Hall Hospital, Brookline, September 25, aged 70 of coronary occlusion

Everett Thomas Zaring ☉ Terre Haute, Ind Indiana Medical College, School of Medicine of Purdue University, Indianapolis 1906, member of the American Society of Anesthetists, deputy coroner of Vigo County, served as secretary for the city board of health, formerly contagious disease physician for the city, on the staff of the Union Hospital, died September 20, aged 61, of cerebral hemorrhage

KILLED IN ACTION

John Arthur Clapp, Chicago, University of Illinois College of Medicine, Chicago, 1942, served an internship at the St Louis City Hospital, St Louis, and the Evangelical Hospital in Chicago commissioned a lieutenant (jg) in the medical corps of the U S Naval Reserve on Oct 14, 1942 began active duty in July 1943, died in the Pacific area July 21, aged 29, of fragment chest wound

Gene W Hair, Buffalo University of Buffalo School of Medicine 1941 member of the American Medical Association diplomate of the National Board of Medical Examiners interned at the Buffalo Hospital of the Sisters of Charity, commissioned a lieutenant (jg) in the medical corps of the U S Naval Reserve on March 12 1943, medical officer on a Landing Ship Tank and had been in North Africa Sicily, Salerno and England, killed in action off the coast of France June 9 aged 35

LIEUT (JG) JOHN ARTHUR CLAPP
(MC), U S N R, 1914-1944

LIEUT (JG) GENE W HAIR
(MC), U S N R, 1908-1944

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of patent medicines," medical devices or cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Bassoran with Cascara—The William S. Merrell Company, Cincinnati, entered into a stipulation with the Federal Trade Commission in March 1944 agreeing to discontinue any advertisement which did not reveal that the product should not be used when symptoms of appendicitis, such as abdominal pain or nausea are present, provided however that the advertisements need only contain the statement "Caution: Use Only as Directed" if the label directions carry a warning to the same effect.

Green's Reliable Restorer—This is put out by an A. J. Green trading as Green's Hair Hospital, Clarksburg, W. Va. In March 1944 he stipulated with the Federal Trade Commission that he would cease representing that his product is not a dye or stain and is harmless, that it corrects gray hair or through use of the term "restorer" or by any other means that it restores the original color to the hair, that it grows or promotes the growth of hair, that it stops the hair from falling out or constitutes a cure or remedy for or has any value in treating dandruff or contagious eruptions, in excess of the removal of dandruff scales.

Gro-Fas Hair Balm Formula "Formula For Treating Gray Hair" and **Gro-Fas Hair Treatment**—These are sold by an H. S. Cobb trading as the Cobb Laboratories, Philadelphia. In a stipulation that he entered into with the Federal Trade Commission in March 1944 he agreed in connection with the sale of Gro-Fas Hair Treatment and the formulas to cease representing that the product itself or one compounded in accordance with his formulas will nourish or feed the scalp or clear it of sore rash or tetter itch. Further he agreed to cease representing by use of the term "Gro-Fas" that the product of this name or one compounded from his formulas will cause the hair to grow longer or in any way affect the growth of the hair. Also he stipulated that he would cease using the word "Laboratory" in his trade name or business when he does not own, operate and control a laboratory where research work in connection with his business is conducted by trained technicians.

Natural-tone—This is a product of a Katherine E. Martin trading as Natural-tone Company, Chicago. According to a stipulation that she entered into with the Federal Trade Commission in March 1944 she will no longer represent by use of the word "restorer" or any other means that the preparation restores the original color to the hair, that it is not a dye, but a gray hair corrector and banishes gray hair, that it makes the hair soft and benefits the scalp, or is a cure or remedy for dandruff or has value in treating it in excess of removing dandruff scales.

Sabetal—This is put out by Isaac Masarsky trading as Hillcrest Laboratories, Spring Valley, N. Y. According to a stipulation that he entered into with the Federal Trade Commission in March 1944 he will no longer represent that the product has any beneficial effect on psoriasis, eczema or any other external skin irritation other than temporarily relieving the itching incident thereto or aids in the removal of loose epidemic scales caused by such ailments. It was further agreed to discontinue any advertisement which did not reveal that Sabetal contains coal tar and oxyquinoline sulfate and that its use may cause irritation and in such cases should be discontinued. Masarsky was permitted however to use the simple advertising statement "Caution: Use Only as Directed" provided that the labeling carried the same warning.

Viet—This is a product of the Cerophyl Laboratories, Inc. of Kansas City, Mo. In March 1944 this concern and the Potts-Turnbull Advertising Company of the same city stipulated with the Federal Trade Commission that they would no longer represent that Viet will relieve or correct such conditions as loss of beauty in skin or eyes, nervousness, undue fatigue, stomach or intestinal trouble, or be beneficial in treating nervous irritability or run-down condition. The Cerophyl concern and the Campbell-Ewald Company of Detroit, another advertising firm stipulated with the Federal Trade Commission to discontinue any advertisement which represented that Viet would help tone or benefit the nervous system, regulate or normalize elimination, reduce susceptibility to colds, build up resistance to illness or disease, or correct some other conditions. They further agreed to cease representing that the use of Viet will be helpful for all conditions resulting from vitamin deficiency, that the grass juice factor in the preparation is essential in nutrition, or that chlorophyll is beneficial or essential in the human diet.

Vilches Cosmetics—These are put out by one Walter Gutheim of New York who trades under the name Mrs. E. Vilches. In a stipulation that he entered into with the Federal Trade Commission in March 1944 Gutheim agreed to discontinue the following advertising misrepresentations: That Vilches Hair Restorer will restore the original color to

the hair, nourish the hair root, promote hair growth or prevent dandruff and falling hair, is not a dye and is harmless; that Vilches Special Hair Tonic will check falling hair; that Vilches Cleaning Cream will cleanse the skin more thoroughly than soap and water; that Vilches Burdock Root Ointment is a cure or remedy for or has value in the treatment of dandruff, itching scalp, itching hair, eczema and other scalp diseases or will promote the growth of hair; or that Vilches Creams, Lotions, Astringents and Powders will nourish the skin, give it a youthful appearance or rid it of wrinkles. Gutheim further stipulated that he would cease representing by use of the words "Skin Food" in the brand name of Vilches Excellent Skin Food or in any other manner that this product will nourish the skin or by use of the words "Pore Cleansing" in the brand name of Vilches Pore Cleansing Cream or by any other means that this cream will cleanse the pores by use of the phrase "Freckle Remover" in the brand name of Vilches Freckle Remover or otherwise that the preparation will remove freckles by use of the words "Pimple and Blackhead Cream" in the brand name of Vilches Pimple and Blackhead Cream or in any other manner that this product will clear the skin of pimples and blackheads.

Vitamelt Enriched Bread—This product put out by Vitamelt Bread, Inc. is reported by the Federal Trade Commission to be enriched with a vitamin powder concentrate manufactured by Dr. W. S. Vitamelt Laboratories, Inc. also of Chicago. In March 1944 the two corporations which are said to have the same stockholders and officers stipulated with the Federal Trade Commission to discontinue the following misrepresentations: That this bread by reason of its impregnation with Vitamelt concentrate provides a competent treatment or efficient remedy for bodily conditions revealed by such symptoms as nervousness, sluggishness, loss of youthful appearance, digestive disturbances, anemia, low vitality, tooth decay, mouth and gum inflammations, insomnia or loss of weight and strength among other disorders; that the vitamin and mineral enrichment of Vitamelt Bread exceeds that of standard enriched bread; that the ordinary diet is apt to lack the necessary amounts of essential vitamins or that it is usually impossible to obtain the requisite quantities of vitamins in the ordinary diet; that for the maintenance of bountiful health, only a reasonable amount of additional vitamins is required for consumers of Vitamelt bread or that the product may be relied on to provide the minimum daily requirements of the essential vitamins and minerals when taken in customary quantities. Further, the two concerns agreed to cease designating the alleged functions of certain vitamins and minerals, such as calling vitamin B₁ the "calm nerve," vitamin iron the "red blood mineral," and calcium the "good teeth mineral."

Woda Polska (Polish Water)—This is put out by Anthony Worzalla, Rose Worzalla, Imber Evelyn Worzalla, Witkowski and Walter S. Worzalla trading as Imber Stevens Point, Wis. According to a stipulation that they entered into with the Federal Trade Commission in March 1944 they will cease representing by the use of the word "restores" or any other means that their dye restores the original color to hair, eliminates or corrects gray hair or is harmless.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Hodgkin's Disease Allegedly Aggravated by Trauma—Hall apparently suffered from Hodgkin's disease prior to the industrial accident here in question. In the course of his employment he operated what is referred to in the opinion here reported as an "oil service unit" sitting on a seat from which he could reach various levers. The unit was tied down by a chain to a cement corner 3 or 4 feet high to keep it from slipping. One day in March 1942 this chain broke, permitting the unit to move forward a few feet against the corner of a derrick and the seat on which Hall was sitting to be thrown up about 8 inches. This caused Hall to be thrown off the seat and on to the ground about 4 or 5 feet below. He was severely bruised on his left hip on the calf of his left leg and on his left arm between the shoulder and the elbow. The next morning he complained of soreness and stiffness in his neck, but there was no bruise visible in that area. While his injuries "troubled him with his work" he continued to work until July 26. Less than a week after the industrial accident a lump formed in the gland under his left jaw, increasing in size until it was about 3 inches long and 1½ inches high. It caused him no pain or particular inconvenience for a few months but some time in June became troublesome. In August 1942 he was taken to a hospital where the gland was removed by Dr. Chesky who made a diagnosis of Hodgkin's disease. The workman died the following February from that disease. His widow instituted compensation proceedings under the workmen's compensation act of Kansas claiming a causal connection between the industrial accident and Hall's death. From an order of the compensation commissioner denying com-

compensation the widow appealed to the district court McPherson County which found that Hall had been suffering from Hodgkin's disease prior to the industrial accident and that the progress of that disease was aggravated and accelerated by the industrial accident, which in turn resulted in Hall's death. The court accordingly awarded compensation and the employer and his insurer appealed to the Supreme Court of Kansas.

The appellants contended that there was no competent evidence before the trial court to support a finding that the progress of Hodgkin's disease in Hall was hastened, aggravated and accelerated by the industrial accident thereby hastening Hall's death. Thus, said the Supreme Court presents a question of law. In deciding the question this court does not weigh the evidence but only examines the record to see if there is substantial, competent evidence to support the findings of the trial court and in so doing ignores controverting evidence which may not have been given credence. We have no occasion here to write a thesis on Hodgkin's disease. However, from the evidence in this case and from pertinent authorities it appears that Hodgkin's disease is characterized by an enlargement of the lymphatic glands, accompanied by progressive anemia and terminating in a fatal result. It most frequently shows itself in the glands of the neck but may involve other glands, as those under the arm, the abdomen or the groin. Sometimes the spleen is affected, and less frequently the liver and bone marrow. As the gland enlarges a real change takes place in the cell structure. Sometimes this suggests an unusual variety of tuberculosis of the lymphatic glands, at other times it is thought to be identical with one variety of a malignant tumor. The disease begins slowly and without pain, and one may be afflicted with the disease for several months or even for several years without knowing it. The cause of the disease is unknown. The progress in some cases has been slowed by treatment with radium or roentgen therapy. The employer and his insurance carrier relied on a quotation from Gray's "Attorneys' Textbook of Medicine," page 526 (ed 2, p 789) to the effect that medical authorities agree that Hodgkin's disease cannot be either caused or aggravated by injury. That thought continued the court, is expressed by the author of that textbook in two other places in his article on Hodgkin's disease, but no medical authority is cited to that effect nor is such medical authority cited by the employer and his insurance carrier and our own research discloses none. Without regard to the correctness of the authority so relied on by the appellants, the trial court was compelled to decide this case on the evidence before it, and our sole question is whether or not there was substantial, competent evidence to sustain the finding and judgment of the trial court. On that point the best that can be said for the appellants is that the evidence was conflicting. Five physicians testified. One of them stated that he did not know the cause of Hodgkin's disease for which reason he would express no view as to whether it might be caused or aggravated by trauma. Two physicians testified that in their judgment trauma would injure tissues affected by Hodgkin's disease just as readily as it would injure healthy tissue or tissue affected by any other disease and in their opinion that, since Hall suffered pain and discomfort in his neck the morning following the industrial accident and a lump formed in a gland in the neck within a few days after the accident, it was reasonable to suppose that the injury had some thing to do with it and that probably the injury aggravated the disease and shortened the life of the workman. Two of the physicians gave it as their opinion that Hodgkin's disease could not be aggravated by trauma, basing their testimony largely on the fact that the medical authorities do not mention trauma as either a cause or an aggravation of the disease. One of the latter physicians testified that he had never had a case in which he was sure that the disease had been aggravated by trauma. The weight to be given to this evidence concluded the court was for the trial court and not for this court on review. It is well settled of course, that an injury which aggravates an existing disease or accelerates the death of a workman is compensable. The employer and his carrier however argued that the medical testimony relied on by the trial court to show a causal connection between the industrial accident and the ensuing death went no further than to indicate that it was possible that the disease was aggravated by the accident and that therefore the judgment of the court was founded on speculation or

surmise. We think answered the court, however that the evidence is not open to that interpretation but went further to the effect that the injury probably had the effect of aggravating and accelerating the disease.

Accordingly the award of compensation for Hall's death was affirmed.—*Hall v Kornfeld-Harper Well Servicing Co* 151 P (2d) 688 (Kan 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1944 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Surgical Management of Wounded in Mediterranean Theater—A highly significant and far reaching advance in military surgery has taken place in the base hospitals with the development of what may be called "reparative surgery." Reparative surgery according to Churchill is not to be confused with the reconstructive surgery of the zone of the interior. Reparative surgery is designed to prevent or cut short wound infection. If the initial wound operation has been a complete one, wounds of the soft parts may be closed by suture on or after the fourth day. The dressing applied in the evacuation hospital is removed under aseptic precautions in an operating room of a general hospital at the base. Following closure, the part is immobilized preferably by a light plaster encasement or, if this is not practical by bed rest. Decision to close a wound by suture is based solely on an appraisal of the gross appearance at the time of removal of the dressing. Preliminary bac-

teriologic analysis of the flora of the wound does not provide information pertinent to this decision or allow the prediction of the result. Clean wounds that heal by first intent on after delayed closure may show a profuse and varied flora, both anaerobic and aerobic. It is estimated that during the Italian campaign alone at least 25,000 wounds of the soft parts have been closed on the basis of gross appearance only. Healing has resulted in approximately 95 per cent, and no loss of life or limb or serious complications have been reported. Four to ten days is the "golden period" to close wounds, reduce and fix fractures, remove retained missiles and carry out other procedures to prevent or abort infection. It is a satisfaction to note the contrast between the present concept of wound management and the doctrines in vogue scarcely a year ago. The closed plaster management of wounds and fractures was designed to conserve life but exacted a high price in skeletal and soft part deformity. Its use is now limited to certain cases with established infection of bone or with massive defects of soft parts complicating a fracture site. Resuscitation measures that relied on plasma alone to compensate for loss of whole blood prolonged life but tied the hands of the surgeon in the performance of life saving surgery.

Penicillin in Surgical Infections—Lockwood and his associates of the Subcommittee on Infected Wounds and Burns of the National Research Council report a series of 400 cases treated with penicillin. The drug when administered systematically modified the course of most infections in which the causative organism is sensitive to penicillin in vitro. The magnitude of the effect in individual cases may be classified as follows: (a) Dramatic curative responses in disseminated sepsis particularly where circulation in localized distributing foci is adequate to effect contact between drug and bacteria. In such cases surgical treatment which would have seemed unavoidable in the past may with penicillin, be postponed or avoided altogether. (b) Favorable responses characterized by subsidence of toxemia, correction of anemia, rapid healing of infected or seriously contaminated wounds and elimination of infection within the pleural cavity or joints. (c) Failures particularly where the organism is insensitive or where the lesion under treatment is attributable only in part or not at all to the persistent activity of penicillin sensitive bacteria and under conditions in which penicillin cannot be brought to the infected area because of poor circulation or limited transport of the drug. Local penicillin therapy needs further study but is yielding encouraging results in special cases. Just as with the sulfonamides the use of penicillin requires a thorough redefinition of the indications for, and objectives in the employment of surgery in treatment of localized infections. Careful bacteriologic studies are essential if penicillin is to be used with maximal effectiveness. As the supply of penicillin increases it will be possible through careful observation of cases and the use of controls whenever practical to reach a more accurate definition of the scope and limitations of penicillin than is yet possible.

Phlebothrombosis of Brain in the Newborn—Marburg and Casamajor state that phlebothrombosis and phlebostasis are frequently the cause of severe disintegration of the brain in early childhood. The site of the lesions corresponds to the drainage areas of the veins. In the 2 cases reported the site corresponded to the drainage areas of the vena cerebri magna and the sinus longitudinalis superior. But whereas in the first case only the drainage system of the vena terminalis anterior and the vena lateralis ventriculi was damaged in the second case the other branches of the great cerebral vein were also affected except for the vena septi pellucidi and some branches draining the corpus callosum and the posterior part of the

superior frontal gyrus. This region was preserved in both cases. That other branches of the vena cerebri magna were affected in the second case is evidenced by the fact that the hippocampal region had not been spared, in contrast to the condition in the first case, the optic nerve showed atrophic changes and the choroid plexus was sclerotic. The pathologic changes are necrosis, malacia and serous perfusion, followed by total or partial destruction of the tissue, with sparing of the most resistant parts (glia) and destruction of the least resistant structures (myelin sheaths and axons). The repair depends on the degree of destruction. Complete destruction is followed by cyst formation, and incomplete destruction by sclerosis. The condition under discussion is closely related to diffuse sclerosis occurring in childhood, which to some extent is only the terminal stage of a phlebothrombotic or a phlebostatic state. The same relation seems to apply to a disease in lambs called "swayback." Cushing performed operations in 4 cases of cerebral hemorrhages caused by birth. Success was obtained in 2 of these. However, since surgical cure is impossible in cases with necrosis, malacia or serous perfusion, prevention is essential, which implies caution during pregnancy, delivery and early infancy.

Mechanism of Alloxan Diabetes—Goldner and Gomori describe experiments on dogs which revealed that alloxan exerts its diabetogenic effect by a direct action on the pancreas. The early hyperglycemia after alloxan is not a causal factor in the development of diabetes. Even if a normal blood sugar is maintained for an initial period after alloxan injection, islet cell degeneration and diabetes develop. The initial hyperglycemia depends on the presence of an intact adrenal medulla. Alloxan

does not inhibit or inactivate insulin. The transitory alloxan hypoglycemia is produced by insulin liberated from degenerating pancreatic islet cells. In alloxan diabetes the insulin content of the pancreas is greatly decreased. The diabetogenic action is a specific property of alloxan. None of the chemically related compounds tested have a similar effect on carbohydrate metabolism.

Cold Susceptible Globulin Fraction of Pathologic Sera E Wertheimer and L Stein —p 1082

Vasospastic Factor in Serum in Raynaud's Disease—Benians found in a patient with Raynaud's disease that her serum contained cold autohemagglutinins. The serum had a high titer of cold antibodies. It was found to cause fatal pulmonary artery spasm in rabbits when given cold intravenously. This effect was mitigated by giving the serum warm. It is suggested that these cold antibodies have a direct effect probably of an allergic type, on arterial musculature both in the experimental animal and in the clinical case. The frequent association of cold antibodies with a Wassermann like body points to an origin of the former from diseased vascular structures, and this again would help to explain their action on both blood cells and vessels. Cold agglutinins are a normal constituent of the blood plasma. They might possibly have a function in the normal vascular control. This function would lie in stopping the blood flow in an excessively cooled part at the periphery and so preventing further loss of heat in the blood still circulating. Preliminary experiments in protection against the cold antibodies by the intravenous injection of lipoids have

been carried out with some success. The author stresses that the point at issue is that arterial spasm results directly from the action of "cold antibodies." The experiments relate to the serum of a patient which contains cold panhemagglutinins in high titer and some lysins. This patient suffered from Raynaud's syndrome when cooled and when really cold, exhibited a condition that may be called shock, with a feeling of constriction in the chest, shortness of breath, pale pinched facies and blueness of the extremities. Her serum injected cold into rabbits caused lysis with rapid death due to spasm of arteries. It seems likely that this violent effect in the rabbit has its counterpart in a mild and reversible form in the patient and that both could be regarded as allergic phenomena.

Chyl thorax in Infancy—Forbes reports a case of chylous effusion in a 6 week old infant with spontaneous bilateral chyl thorax. The problem of maintaining a state of adequate nutrition in this type of patient is an important one, as the withdrawal of large amounts of chyle rich in both fat and protein must be repeatedly carried out in the course of the treatment to relieve and prevent severe dyspnea. Some observations have been made on replacement of the aspirated chyle intravenously. In some reported cases this procedure was of considerable benefit, in others it effected no response and in still others sudden death took place which was interpreted as an anaphylactic reaction. Since chyle normally enters the systemic circulation by way of the subclavian vein, it seems unlikely that such reactions could occur entirely as a result of anaphylaxis. In the case here reported considerable amounts of the chylous fluid were injected intravenously without ill effects. However the child succumbed despite repeated thoracenteses and vigorous

supportive therapy over a period of two months. Postmortem examination failed to reveal a cause for the chylous effusion. Absorption tests with vitamins A and D and beta carotene were performed. Vitamins A and D were rapidly absorbed into the chyle from the gastrointestinal tract and in appreciable quantities. Beta carotene was poorly absorbed. Aspirated chyle was administered intravenously many times without untoward reactions. The loss of protein through the repeated aspiration of chyle is fully as important as that of fat, if not more so. Supportive therapy in cases of chyl thorax should include measures to maintain body protein stores.

Congenital and Infantile Beriberi—Van Gelder and Darby describe a case of congenital beriberi. The infant was cyanotic and almost aphonic, with extreme tachycardia and a greatly enlarged heart. Spectacular improvement resulted from the use of large parenteral doses of thiamine hydrochloride. Urinary thiamine assays and dextrose, pyruvate and lactate blood levels, fasting and following ingestion of dextrose, indicated a state of thiamine deficiency in the mother. Despite a wholly inadequate antepartum diet the mother did not exhibit clinical signs of beriberi. Although the mother had a subclinical attack of beriberi, the infant was born with severe, almost fatal, manifestations. It is difficult to explain this difference in degree of objective evidence of avitaminosis between mother and infant, but the case illustrates well that one should be on guard when a pregnant woman has been subsisting on a poor diet. The authors suggest that some cases of "congenital idiopathic cardiac hypertrophy" or "status thymicolymphaticus" may actually be instances of unrecognized congenital or infantile beriberi. Infants with large hearts in whom no valvular or congenital lesion can be demonstrated should be given large parenteral doses of thiamine hydrochloride as a therapeutic test. During pregnancy and lactation a mother should be provided with an adequate intake of vitamin B. If the maternal diet is suboptimal, the nursing infant should receive additional vitamin B, until such time as other foods containing this vitamin are introduced.

Streptothricin as Chemotherapeutic Agent—Robinson and Smith report on the efficacy of crude streptothricin in a variety of bacterial infections and also in infections produced by *Trypanosoma equiperdum* and the virus of epidemic influenza. In vitro and in vivo studies showed that crude streptothricin possesses great activity against a variety of gram negative bacterial species. Gram positive forms are also sensitive to the action of streptothricin, but not to the same degree as the gram negative forms. The activity of streptothricin is not influenced by blood serum peptone or vitamins of the B complex. Streptothricin is more active when given parenterally than when administered by mouth. The drug is not active against the virus of epidemic influenza or *Trypanosoma equiperdum*. The ultimate chemotherapeutic index of streptothricin will depend on the toxicity of the pure product. The results suggest that streptothricin may be useful in the local treatment of infected wounds and burns as well as in bacillary dysentery typhoid and food poisoning produced by the *Salmonella* organisms.

Renal Calculus with Parathyroid Adenoma—A woman over a period of several years had formed stones in both kidneys. Although her blood calcium was significantly raised, the normal blood phosphorus and the oxalate type of stone and lack of bone changes led Foulds to abandon the diagnosis of hyperparathyroidism. Eight years later, when unmistakable findings were present, such as bilateral renal calculi, bone pain, fatigue, weakness, x-ray evidence of osteitis fibrosa cystica, elevated blood calcium levels and decreased blood phosphorus levels, the correct diagnosis was made and proved by operation and pathologic examination of the adenoma which had been removed. The diagnosis could have been made earlier had the author appreciated the full significance of his earlier findings.

Abnormal Carbohydrate Metabolism in Burns—Taylor and his associates review observations on 35 consecutive patients with burns admitted to the Boston City Hospital. These patients exhibited a high incidence of hyperglycemia, lacticacidemia and a moderate reduction in the carbon dioxide combining power of the plasma. There is a high degree of correlation between these abnormalities of carbohydrate metabolism and the severity of the burn. The few glucose tolerance tests that were made indicate that in some severely burned patients with hyperglycemia there remains a considerable ability to metabolize added glucose. There was no evidence of liver damage in these patients as a result of the burn injury. In the few cases in

which liver damage was found it was present before the injury, being for the most part an alcoholic cirrhosis. The described abnormalities in the carbohydrate metabolism are not inconsistent with the presence of an increased glycogenolysis together with a possible gluconeogenesis from protein.

History of Public Health in Chautauqua Cattaraugus and Allegany Counties H R O'Brien—p 2132
*Diphtheria in Adequately Immunized Community B F Mattison—p 2138

Frost Injuries in Warfare—Liebesny differentiates seven types of frost injuries: (1) erythema and edema, (2) blisters and bullae, (3) superficial gangrene, (4) gangrene of skin and subcutaneous tissue, (5) gangrene of a whole part of an extremity or other parts of the body, especially the ears, (6) injury to muscles, tendons, periosteum, bone and nerves without or with accompanying lesions of the skin, (7) chronic relapsing lesions of the skin, e.g., chilblains and other forms of erythrocytosis. Application of heat in frostbite is inadvisable. This is true in first aid as well as in treatment. The defrosting of frozen parts must be done by means of wet dressings with water of 41 to 58 F. Rubbing or massaging of the frozen parts should be avoided. The therapeutic effect of refrigeration in frostbite may be explained partly by its antiphlogistic effect and partly by the fact that it permits only a gradual increase in the temperature of the frozen parts up to normal body temperature, so that there is sufficient time for the improvement of circulation. To achieve improvement in the circulation, short wave therapy of low intensity has been found effective by the author and by Italian clinicians. The short wave current is applied with air spaced electrodes. The treatments are given daily for ten minutes. The current is applied in such a manner that the increase of the temperature of the skin in the treated area does not exceed 0.5 degree C after ten minutes of application. Recovery is usually accomplished with few treatments. Leriche and Knuln recommended anesthetic infiltration of the lumbar and stellate sympathetic in patients suffering from frostbite with edema and pain. Nearly all patients were immediately relieved. The infiltrations were repeated on the following two days. If there was no necrosis or infarction, patients were well in a few days. Transfusions of plasma in patients suffering from frostbite of large areas and of high degree are advisable. These transfusions should be given during the first twenty-four hours.

Diphtheria in an "Adequately" Immunized Community—Mattison reviews an outbreak of diphtheria in Kingston, N. Y., a city with a population of 28,000. The previous history of this city with regard to natural and artificial immunity was unusually complete. An extensive Schick survey had been made in 1922 and again in 1938 together with a carrier survey at the later date. The carrier rate had been 0.03 per cent and there had been a decreasing natural immunity. Twenty-eight cases occurred in the 1943-1944 epidemic. The nature of the disease, in general, was mild, especially when toxoid had been given at some earlier date. An analysis of the immunization histories of 1,160 school children indicated a history of past immunization in 75 per cent reported immunizations among preschool children at the beginning of 1943 indicated that 44 per cent of them were protected. The epidemic occurred predominantly in school age children all of whom had either not been protected, had been given less than the currently recommended toxoid dosage or had been immunized five or more years earlier with no subsequent restimulation. With the available data it is not possible to know whether the outbreak was due to some one or a combination of all of these factors. The decreasing prevalence of diphtheria has brought with it decreasing natural resistance to the disease. Levels of artificial immunization formerly adequate to protect a community may no longer suffice. Suggested steps to maintain the necessary level of community protection

include higher preschool protection rate reimmunization of all children on entrance to school and administration of complete courses (two doses of alum precipitated toxoid or three doses of fluid toxoid) in every individual immunized

 *Relation of Ovarian Function to Uterine Fibroids E M Baker —p 29

Remissions of Diabetes Mellitus—According to Lukens and Dohan a remission of diabetes means that the disease has so improved that the blood sugar stays at a normal level without insulin treatment on a diet sufficient to maintain normal weight and strength. Such patients frequently have some abnormality as shown by the glucose tolerance test, and diabetes will usually manifest itself during an infection. Remissions must be distinguished from the normal state in which the tolerance test shows a normal curve and the carbohydrate metabolism is not grossly disturbed by infection. The authors surveyed 517 diabetic patients attending their clinic in the past two years. Of this number 19 (3.7 per cent), in whom the diagnosis of diabetes was unquestionable, were on an adequate diet without insulin for periods of from one month to ten years. In 4 of the patients improvement occurred after dietary treatment alone, in 6 it followed active insulin treatment combined with recovery from infection and in 9 it resulted from insulin treatment in the absence of complications. The authors feel that the patients of the last group fulfil their criteria most completely, and these 9 remissions in 517 patients give an incidence of 1.7 per cent. This may be compared with 1.4 per cent cited by Joslin. Seventeen of the 19 patients who had remissions were first seen within four months of the onset of diabetes. This fact deserves emphasis because it stresses the value of early treatment. With the possible exception of infection, the most impressive diminution in the severity of diabetes is seen in the mildly affected obese diabetic patients who respond so well to diet and weight reduction. Many writers have noted the impaired glucose tolerance and diminished response to insulin after high fat diets and the full response to insulin after high carbohydrate diets even when these are low in calories. The previously untreated diabetic patient, after prolonged thorough treatment with diet and insulin, responds with a distinct decline in the insulin needed.

Relation of Ovarian Function to Uterine Fibroids—Baker reviews a series of 36 cases of uterine fibroids. He believes that there is sufficient clinical and pathologic evidence to support the theory that a cause and effect relationship exists between the unopposed and persistent action of the estrogenic principle produced by multiple follicle cysts of the ovaries on the uterine endometrium and myometrium producing immediate endometrial hyperplasia, and, when the stimulation is sufficiently prolonged, uterine fibroids. All forms of overgrowth of the uterine endometrium and musculature are due to the same factor, namely the estrogenic hormone.

Rheumatic Fever in Canadian Army—Acute (febrile) polyarthritis of unknown etiology is the term used in the Canadian army to designate a condition characterized by swollen joints, fever, rapid pulse and elevated sedimentation rate. Patients with this disease respond well to rest and salicylate therapy. Feasby reviews the 407 cases of "polyarthritis" and acute rheumatic fever which occurred among army personnel in Canada during 1943. It was found that about 4 per cent of persons with streptococcal disease of the respiratory tract acquired polyarthritis. The incidence of polyarthritis closely follows the incidence of streptococcal disease of the respiratory tract. Ninety per cent of the cases occurred in the first seven months of the year. Military populations most seriously affected were those of Saskatchewan and Alberta. No particular strain of streptococci accounts for these cases or their complications. The commonest type was A 19, which was predominant in the 1943 streptococcal epidemic at Camp Borden, Ontario. Follow up of the 407 patients revealed that 24 had cardiac complications. A total of 242, or 60 per cent, of the 407 patients with polyarthritis have been discharged and may be pensioned. Sixty-six of these had other conditions which were of greater importance as the cause of discharge. Twenty-three per cent of the patients are still on full duty and 17 per cent are on limited duty. Preventive measures include proper dust control in sleeping quarters and adequate hospital isolation of persons with streptococcal illness.

Gramicidin S and Its Use in Treatment of Infected Wounds—Gause and Brazhnikova studied the clinical application of gramicidin S in 573 cases. The original 4 per cent alcoholic solution of gramicidin was diluted with water to make the concentration of gramicidin 400 to 800 micrograms per cubic centimeter of the liquid. These solutions were applied daily either locally or introduced into cavities. The results can be summarized as follows. The first group included cases of septic gunshot wounds of the hip, suppuration following heavy burns of the abdomen, breasts, hips and hands, abscesses of the abdominal wall, heavy anaerobic phlegmons and others. The application of gramicidin S led to (1) rapid disappearance of bacteria in the wound and successful epithelization, (2) successful preparation of the wound for subsequent surgical treatment and (3) in some cases disappearance of the septic state through elimination of the local suppurative process. Gramicidin S was used also in cases of septic gunshot wounds of the larynx and chronic otitis, in empyema and in osteomyelitis.

Effect of Aluminum on Lung in Grinders of Duralumin

—Hunter and his associates investigated the health of airplane propeller grinders. A comprehensive study of the environmental conditions was carried out in a particular factory, and physical analyses of the atmosphere content of aluminum have been made close to the grinders' mouths and in the general atmosphere of the shop. All the grinders and polishers of propellers in one factory were interviewed and their occupational histories were taken. Twenty-seven claimed to have some cough and 10 to be somewhat short of breath but these symptoms did not appear to cause them inconvenience. The sick records of the group were examined and compared with a similar group of workers in a machine shop belonging to the same company. This analysis showed no difference of statistical significance between the two groups. Blood counts and x-ray examinations were made on duralumin propeller grinders. Fifteen by 12 inch roentgenograms were taken in 92 of 97 workers who were exposed to aluminum dust. There was no evidence in any of them of reticulation. In 7 instances there were shadows in the peripheral part of the lung which were different from the ones usually found in this situation. It is conceivable that they may be due to concretions of aluminum dust. They were not related to symptoms. The authors conclude that there is no evidence that the dust to which the grinders are exposed produces any disease of the trachea, bronchi or lungs.

Subcutaneous Emphysema Due to Compressed Air—

Whitwell states that, apart from its use with pneumatic tools, compressed air is commonly used in the engineering industry (a) as a coolant and (b) to blow away metal particles from the cutting area of machine tools. If the operator has already sustained skin trauma there is a risk of air entering the wound and causing subcutaneous emphysema. A piece of metal pierced the pulp of the middle left finger of a man while he was milling a steel component. He removed it and continued to work, holding the components in his left hand while he used the compressed air on them. In a few minutes the injured finger had become white. The terminal part of the finger was white, insensitive and slightly tense. An hour and forty minutes later he had the typical 'crackling' swelling of emphysema over the dorsum of the hand and on the radial side of the extensor surface of the forearm as far as the elbow. There was no further extension of the swelling but the finger was then red and aching. He was sent home, and the condition disappeared within twenty-four hours. No sepsis developed and there were no untoward results.

Polyneuritis, Particularly Acute Varieties—Pirzada observed 6 cases of acute polyneuritis in a period of about two years. During the same period he observed only 5 cases of chronic polyneuritis. The essential feature of acute infective polyneuritis is extensive paralysis of sudden onset from which the patient recovers rapidly if he does not succumb. Three cases of this type are described. The disease appears to be relatively benign, possibly because of infection with a virus of low virulence. A less acute and milder form of polyneuritis with a protracted course and of unknown etiology is described by Walshe. Three cases described in the text belong to this variety. In the cases observed by Pirzada, however, syphilis appears to be one of the etiologic factors. Vitamin B₁ deficiency is not believed to play a part in the direct causation of acute polyneuritis, but it has been suggested that subclinical deficiency may be a predisposing factor and a specific virus and Treponema pallidum precipitating factors. The efficacy of vitamin B₁ therapy in polyneuritis, particularly in the acute forms, is open to doubt, but Pirzada's experience suggests that it is worthy of further trial under controlled conditions. In chronic polyneuritis an etiologic factor can usually be found. In the 5 chronic cases mentioned by the author leprosy, nutritional factors, diabetes and typhoid were etiologic factors.

- *Acute Nontuberculous Pleural Empyema M Gonzalez Ribas—p 553
Endometriosis of Genital Organs J M Bedoya Gonzales—p 594

Acute Nontuberculous Pleural Empyema—Gonzalez Ribas practiced closed drainage with intrapleural aspiration according to Monaldi's technique in 9 cases of acute nontuberculous pleural empyema. The condition was secondary to septic infarct following gynecologic operations in 6 cases, to pneumonia in endocarditis lenta in 1 case and to lung abscess in 2 cases. The drainage was carried on for periods of two to six weeks. Three patients recovered. One patient improved. He had to have a pleurotomy complementary to drainage, after which he recovered. Two patients died from new pleural foci shortly after control of the early pleural foci. Two patients died late after control of pleurisy. One died of acute atrophy of the liver and the other from heart insufficiency. A necropsy in the 4 cases showed complete reexpansion of the lung and consequent closure of the pleural cavity. Trauma caused by the establishment of the drainage is minimal. The pleural fluid is removed at a slow rate, and the consequent decompression of the mediastinum is effected slowly and progressively. In very acute cases the procedure can be carried out with the patient in his bed. Rapid sterilization of the pleuritic fluid is obtained in all cases. Reexpansion of the lung and permanent closure of the pleural cavity are obtained in almost all cases. In the rare cases in which the closure of the pleural cavity is not complete the condition of the patient is improved to such an extent that he can have the proper surgical intervention. In rare cases however, new foci of empyema appear either in the lung areas which were previously normal or in the opposite lung. The course of new foci is fatal. Closed drainage with intrapleural aspiration prevents early postoperative mortality and the development of chronic empyema and of open pneumothorax. The patient can have the proper medical and supportive care in the course of the therapy.

Book Notices

Heart Disease By Paul Dudley White M.D. Physician to the Massachusetts General Hospital Boston Third edition Cloth Price \$9 Pp 1 025 with 138 illustrations. New York Macmillan Company 1944

The first edition of this book was published in 1931, the second in 1937. Just as the second edition was a vast improvement over the first, so the present volume is further along the road to perfection. The arrangement of the book has not been greatly altered, but it is apparent throughout that the author has taken great pains to revise it in accord with current advances in the cardiovascular field and also to meet the major criticisms made of the earlier editions. As a veteran hewing close to the line, he separates fact and fancy. Hypothetical and unsettled issues are mentioned but not labored, they are, as the author states in his preface, 'dismissed with remarks which summarize what we know and what we don't know about them.' In accomplishing this admittedly difficult task, he has enhanced the value of his book as a textbook for students as well as a reference book for practitioners.

Appearing for the first time in this edition is a chapter entitled 'The Range of the Normal Heart,' which is probably the most important and valuable addition that the author has made to his book. Retained in this revision, but deleted from the second edition to save space, are original quotations from men whose names are famous in the field of cardiology. An interesting feature is the addendum dated March 1944 which contains material inadvertently neglected after proof reading, and also a brief discussion of the most important contributions that appeared up to the time the book went to press.

The publishers, although handicapped by the paper shortage, have nevertheless produced a volume which compares favorably in appearance with its predecessors. Although it contains nearly a hundred more pages than the first edition, it is smaller, lighter and easier to handle. As an authoritative treatise on the subject it may be warmly recommended to all students interested in the subject of heart disease.

Hospital Color and Decoration By Raymond P. Sloan Cloth Price \$3.75 Pp 253 with illustrations Chicago Physicians' Record Company 1944

There has been a growing realization in recent years that beauty is an essential element in hospital construction. Fortunately this can be achieved without extravagance and without the sacrifice of any of the basic principles involved in the practical utilization of institutional facilities. In the present volume the author shows how cheerful and attractive surroundings can be attained. His principal medium is color, yet he does not overlook the importance of other decorative effects in the planning and arrangement of individual rooms, wards, hospital entrance, lounge, solariums and other units. Careful attention is given to the selection of furnishings, lighting effects, flowers and plants and also to the scientific landscaping of hospital grounds. Excellent illustrations are included and many valuable suggestions, charts and guides with reference to color schemes, plants for the sunroom and outside planting appropriate to the various sections of the United States. A useful bibliography facilitates the selection of other reference material. The book is highly instructive and is written in a pleasing and interesting style. It is a welcome addition to the literature of the hospital field and should be read by all who are interested in hospital construction and service.

Investigaciones sobre fisiopatología tiroidea Por C. Picado T. Publicaciones de la Secretaría de salubridad pública Paper Pp 92 with illustrations San José Costa Rica 1943

This little work stems apparently out of the fact that in Costa Rica in the author's opinion, thyroid dystrophies are due not only to exogenous factors, such as iodine deficiency, but also to endogenous factors. The author believes that special normal physiologic indexes must be established for countries such as Costa Rica, where climate and other factors influence physiologic functions differently as compared with temperate countries. In studying the etiology of Costa Rican thyroid

dystrophies, the author develops a hypothesis advanced in an earlier publication. This hypothesis has to do with the formation of antihormones, and his conclusions fall essentially in line with accepted thought in this connection, so far as the broad principles of antihormone formation are concerned. The author has carried out considerable experimentation on the influence of hormones and antihormones, using serums of various species of animals. As regards human beings, this reaches a focus in the explanation offered for the probable mechanism of the therapeutic action of serum from thyroidectomized animals when injected into hyperthyroid patients. This explanation is that 'the thyroidectomized animal's serum contains an excess of thyrostimulin (acting as haptene) which, with the serum as vector, immunizes the receptor patient against his own excess of thyrostimulin.' The author makes the mistake of endeavoring to include too many lines of work in this brochure, with the result that his chief conclusions are not clearly set forth. To those interested in the relations between thyroid dystrophies and possible etiologic factors this little work may prove interesting. Many of the illustrations in the book and some of the text consist essentially of a reproduction of earlier work.

Proceedings of the Conference on Problems of Human Fertility Sponsored by the National Committee on Maternal Health January 15-16 1943 New York City Edited by Earl T. Engle Cloth Pp 182 with illustrations Menasha Wis George Banta Publishing Company 1943

Criteria of ovulation, sperm migration and placental transmission are discussed in twelve papers. Severinghaus feels that there is a dependable relation between pregnandiol in the urine and corpus luteum formation. Rock and Hertig report on 14 very early ova with average ovulation as day 14 preceding expected menstrual period, and slight deviation. Wislocki compares nidation in monkeys at day 9 with the human day 7½. Hartman is unsure of a monkey safe period, his range of ovulation time in 293 animals being from the 9th to the 23d day. Corner declares that corpora lutea in woman and the monkey can be dated fairly accurately, questioning Hartman's biannual indications. Greulich reports favorably on rectal temperature tests when taken by institution attendants as indicating the time of ovulation with check by 29 laparotomies and microscopic sections. Rubenstein checked on vaginal smears as an indicator of ovulation by 18 laparotomies. Boling gave electrometric technic.

Lamar found that the spermatozoa in vitro would enter cervix mucus collected at any time during the month including that of menstruation. This is in contrast to the Huhner and Weisman in vivo tests, which show entry only at midcycle. Rubenstein estimated intravaginal sperm survival as 30 to 180 minutes. Rakoff induced atrophy of vaginal mucosa with testosterone, and Hertig found estrogenic activity of the ovary long after ovulation ceased.

Other chapters discuss biology of the vagina, cytology of the trophoblast and various aspects of placental transmission. The discussions following the papers bore somewhat on the clinical aspects of the topics.

Varicose Veins Hemorrhoids and Other Conditions Their Treatment by Injection By R. Rowden Foote M.R.C.S. L.R.C.P. D.R.C.O.G. Physician in Charge Injection Clinic Royal Waterloo Hospital London Cloth Price 12s 6d Pp 119 with 54 illustrations London H. K. Lewis & Co. Ltd. 1944

This is a short treatise on the indications and technic of sclerosing injections for varicose veins, hemorrhoids, hydrocele, bursa, ganglion, nevus and anal fissure. There is an appendix of useful prescriptions and some points on the organization of an 'injection clinic.' The text is clear and concise, the illustrations and printing are excellent in spite of having been produced in war-torn England. In 115 pages the author has described and summarized all the practical points of injection therapy. An excellent chapter on the operative treatment of varicose veins has been written by Mr. Rodney Maingot. Unusual for the American reader is the combined use of lithium salicylate with quinine (Maingot's solution), which gives a gelatinous mass and is said to avoid cinchonism. This volume is highly recommended for the general practitioner. It contains all he needs to know about this form of treatment.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CONSERVATIVE AND OPERATIVE MANAGEMENT OF SINUSITIS

To the Editor—I am a retired otolaryngologist who practiced in a great metropolitan city for nearly twenty five years after that went into the first world war and at its close served seven additional years in a Veterans Hospital. I have been retired ten years and though I have a recent standard work on otolaryngology, I do not find just what I am interested in knowing about the present attitude of the best established and most representative otolaryngologists toward operative procedures on the frontal and ethmoid sinuses. Specifically I should like to know what percentage of operations for chronic discharge from the frontal and ethmoid sinuses result in cure. Another thing in my practice I learned that a large number of sinus infections are acquired in swimming pools. The other day a young girl told me that her otolaryngologist had cautioned her against diving because she had sinus trouble. The question arose in my mind whether as she has pustular sinus disease already there could be a reinfection since there are only a few pus forming germs to be considered notably the streptococci and staphylococci. I think that if the doctor had advised a piece of cotton in the nose for comfort he need not have denied her the pleasure of diving.

Fayette C. Ewing MD Pineville La

ANSWER—There are certain cases of an acute nature in which surgery is more dangerous than conservative treatment. On the other hand, there are many fulminating cases of frontal sinusitis which require immediate and complete drainage with wide exposure following operation. The rules which govern general surgery apply here, with necessary allowance for the difference in the anatomic structures involved. Therefore, to lay down a hard and fast rule without qualification and try to treat all cases by this rule is a dangerous policy. Each case must be evaluated on its own merits, with or without operation according to the indications present.

A chronic frontal sinusitis or ethmoiditis may be so severe that it may be necessary to operate if an acute exacerbation develops.

The most urgent indication for surgery in frontal and ethmoidal infections would seem to be when one is confronted with the acute fulminating type with threatened orbital or intracranial complications.

When a chronic ethmoidal or frontal infection has not responded well to intranasal procedures, and in polypoid conditions with or without suppurative, a definite indication for surgical intervention is present. In frontal sinusitis when the x-ray studies reveal chronic thickening or polypi associated with headaches, surgery of the frontal sinus should be considered.

Where such gross pathologic change cannot be demonstrated and only a discharge persists with sufficient room for aeration and drainage, then certainly conservative treatment should be given a trial, with use of shrinking solutions and packing the diseased area with colloidal silver or tyrothricin. If results have been unsatisfactory after a reasonable time, intranasal surgery such as removal of the anterior third of the middle turbinate together with uncapping of some of the suspected ethmoidal cells or enlarging of the frontal ostium (not rasping) should prove beneficial.

If such surgical attacks do not produce the desired results, a Sewell or Killian operation limited to the frontal and ethmoid sinuses should give results. In a small frontal sinus the Sewell operation, in which the floor of the frontal sinus is removed together with the diseased mucous membrane, should be considered. However, in a large frontal sinus associated with considerable involvement of the ethmoidal cells a Killian operation in which the anterior wall and floor of the frontal sinus is removed, leaving only a bridge to prevent a deformity, would seem to be the operation of choice, because the diseased areas are more easily visualized and removed. Such procedures should give results if all the diseased tissue has been removed.

There are many opinions but no statistics on the percentage of cures in sinus infections, whether by medical treatment or by any of the surgical procedures.

Many reports have appeared regarding patients with chronic sinus infections who go in for diving. Sinus infection has been aggravated by diving, and often the severe type has developed not infrequently complicated by osteomyelitis. Whether or not new organisms are introduced does not seem to matter, the important observation is that such fulminating cases are frequently reported. It would therefore seem inadvisable for a

patient with sinusitis to be exposed to the possibility of developing an infection of the frontal sinus from the adjacent anterior ethmoid cells and the possible associated severe complications.

Packing a nose when diving may possibly be helpful, as it may slow the sudden ingress of water into the nasal cavities but it also may interfere with the proper respiration of the swimmer.

Accounting for the apparent differences in methods of treatment, several things should be considered important such as the climate or section of the country and environment in which the patient must live and the actual occupational and hygienic conditions under which he works. Also to be considered are the social status or mental capacity of the patient that is whether he can or will follow out conservative or postoperative treatment and care. It is undoubtedly true that more conservative measures are successful under the climatic conditions found in warmer places such as Louisiana, Florida and the Carolinas than is possible in New York with its more rigorous and changeable climate. For this reason reports from Louisiana of excellent results from conservative treatment of acute or sub-acute sinus conditions may be expected. Another specialist who lived in the North might take exception because he argues from entirely different premises.

PLEURAL FRICTION RUB WITHOUT PAIN

To the Editor—I have recently observed 2 patients with pulmonary tuberculosis who had pleural friction rubs without pleural pain. Neither patient showed evidence of pleurisy by x-ray. In each case the pleural friction rub was followed in several days by pleural pain at which time the rub disappeared. This seems to me to be paradoxical and I am unable to find any reports in textbooks or in the *American Review of Tuberculosis* the only journal on file here which mentions or confirms my findings. I am considering writing an article on these 2 cases because I feel that the subject and my findings would be of interest. Do you have any articles or additional information on the subject? M D West Virginia

ANSWER—There are no sensory pain fibers in the visceral pleura over the periphery of the lung, but the parietal pleura is richly supplied with them. Therefore pain is experienced only when certain involvement occurs in the parietal pleura. Occasionally one sees a patient who presents pleural friction rubs which can be elicited both by palpation and by auscultation in the total absence of pain. Some patients are conscious of a rubbing sensation but experience no discomfort.

The involvement of the parietal pleura may be an extremely mild and slow process, and the thickening takes place so gradually that the pleura adapts itself to the changed situation just as occurs in some slowly developing conditions in the skin. So much fibrous tissue is deposited around the nerve endings that they are not stimulated when friction is first elicited. When either the visceral or the parietal layer of pleura or both becomes inflamed, the visceral layer glides over the parietal layer but not so smoothly as usual. There may be an absence of sufficient serous fluid to lubricate adequately the area under the changed condition. Apparently it is only when the visceral pleura begins to cling to the parietal layer that pain is experienced. This causes some tugging or pulling on the parietal pleura, which is richly supplied with sensory pain nerve fibers. In cases in which pleural effusion forms and accumulates early it serves as a wedge, and unless the two layers of pleura are firmly adherent at certain points they are separated and the pain disappears. In the event that fluid does not accumulate the pain is likely to persist until adhesions immobilize a large area of visceral pleura or the parietal pleura becomes adapted to the changed condition.

It has been suggested that in some cases of pleural friction in which pain is never experienced, the parietal layer does not become inflamed and adhesions do not form. The inflammation is confined to the visceral pleura and is self limited. A remote possibility in cases in which pain never occurs is the existence of an area of anesthesia involving the parietal pleura (compression, girdle and segmental anesthesia).

This is an interesting subject, and a summing up of available information together with the presentation of the 2 cases would be worth while.

IMMATURE CATARACT

To the Editor—I have a cataract which is not ripe enough to be operated on. I am using daily 1 per cent homatropine instilled in the eye in order to get a larger visual field. One ophthalmologist approves but another one says that it may cause some local trouble by keeping the pupil dilated. Do you think that the second one is right? M D New York

ANSWER—It is no longer necessary to wait for a cataract to become "ripe," as modern ophthalmic surgery permits the removal of a lens at any stage with safety. If the lens opacity has progressed to such a point that pupillary dilation is necessary for useful vision, intracapsular removal of the lens is indicated.

Continued dilation of the pupil is potentially hazardous. Continued dilation of the pupil may not do harm, but there is always the possibility that the dilated pupil will precipitate an attack of acute glaucoma and then irreparable damage is done. There is no need to run this risk.

URTICARIA AND ANGIONEUROTIC EDEMA

To the Editor—A woman physician aged 35 who had never before been seriously ill was taken sick three weeks ago first with nausea headache and severe vomiting. Twenty-four hours later she broke out with hives of tremendous size at first only on the body later covering the arms and legs. At the same time angioneurotic edema of the eyelids lips hands and feet developed. These attacks came four or five times daily and are much worse during the night. Her condition is getting worse in spite of different treatments. No relief is obtained from local applications except that rubbing alcohol relieves the itching somewhat. She takes one tablet of $\frac{3}{8}$ grain (24 mg) of ephedrine hydrochloride four or five times daily and in addition is given injections two or three times daily of epinephrine 1:1000 0.5 cc each time or epinephrine in oil. That medication gives relief for about four hours. On advice of a skin specialist she was put on a diet which is free of meat eggs wheat coffee and fresh fruit. In the first week nicotinic acid and Calcium tablets were tried with no results. In the second week Torantil tablets (3 x 2) were continued with the Calcium tablet. Finally Hapamin (Parke Davis) is being tried. No relief has been obtained so far. Her general health is good there are no other symptoms or findings. What other treatment could be tried? Can the prolonged use of ephedrine in such a great amount be harmful? The skin specialist advised against any skin tests assuming that we might get a number of wrong reactions because of the great irritability of her skin.

M D New York

ANSWER—Urticaria and angioneurotic edema occur frequently, separately or together. They are usually due to ingestion of certain foods or drugs occasionally they seem to be associated with bacterial infection, especially in the gallbladder. Skin tests in these two conditions are usually of little if any value because positive tests are often found which have no clinical relation to the cause of symptoms, and, in other cases, tests are negative to foods known to cause the swellings. It is known, for example, that strawberries, a frequent cause of urticaria, give an extract which usually shows negative skin tests even in susceptible persons. Benson has shown that such patients can safely eat strawberries if the berries are carefully washed in a colander with hot water. Evidently the allergen can be washed away and is not in the berry itself.

Experience has shown that most patients with urticaria and angioneurotic edema recover more or less rapidly if they avoid (1) drugs and medicines of all kinds (2) pork, including ham bacon lard and Jello, (3) fresh fruits, including juices (4) fresh vegetables, including juices, (5) peas, beans and tomatoes, cooked or raw, (6) chocolate and cocoa, (7) fish of all kinds (8) nuts and (9) cola drinks. This diet should be maintained for about two weeks, if symptoms subside one of these foods is to be added at intervals of four to five days, pork and peaches last of all. If the swellings continue other elimination diets should be tried, e.g. a strict milk free diet. Epinephrine and ephedrine may be used to control large swellings, but calcium and histaminase (Torantil) usually fail. A series of injections of histamine, beginning with 0.10 cc of the 1:10,000 dilution occasionally gives relief. The gallbladder and other possible foci of infection should be studied in obstinate cases.

FAITH HEALING

To the Editor—Frequently I have had occasion to answer well meaning patients with regard to the faith healing of various Catholic shrines such as at St. Ann De Beaupre and at Lourdes. I find myself at a loss for concrete evidence of the psychologic aspects of such miracles. Has any scientifically controlled investigation of these phenomena ever been conducted? What are the conclusions of these investigators both pro and con? Has such an investigation ever been suppressed? I should be grateful for any information you can offer me regarding these queries.

T R Hazelrigg M D Cleveland

ANSWER—It is certain that the suggestion of cure must benefit many persons in these shrines and the advertisement of the cures must certainly make the suggestion for cure potent. On the other hand untold misery is caused to many hopeless sufferers from structural disease and degeneration by their long and useless journeys to shrines from distant places and often far off countries. One must remember that one hears of the cures, the disappointed patient does not advertise his disappointment.

PSEUDOHYPERTROPHIC MUSCULAR PARALYSIS

To the Editor—Please advise as to treatment for pseudohypertrophic muscular paralysis in a boy of 6.

Samuel Marritt M D Sackets Harbor N Y

ANSWER—There is no known treatment that exerts a favorable influence on pseudohypertrophic muscular paralysis.

FIRST INFECTION TYPE OF TUBERCULOSIS IN CHILDREN

To the Editor—I have just read the book review for "The Evolution of Tuberculosis as Observed During Twenty Years at Lymanhurst Minneapolis Board of Public Welfare 1921 to 1941" published in The Journal August 26, 1944 page 1216. The statement is made in the review that, after thirteen years of observation and study, it was decided that treatment of children with the first infection type of tuberculosis is of little avail either immediately or remotely. Was the inference intended that children with the first infection type with low grade fever and failure to gain weight could be permitted to go to school and otherwise lead an essentially normal life for children of that age?

H M Janney M D Ashland Ky

ANSWER—The authors of "The Evolution of Tuberculosis as Observed During Twenty Years at Lymanhurst" state that in their experience low grade fever and failure to gain weight were not found to be manifestations of the first infection type of tuberculosis. They originally had a hospital division where such children were kept strictly in bed and under close medical observation. The symptoms mentioned, as well as others, were invariably found to be due to nontuberculous conditions, such as foci of infection in the nose, mouth and throat. However, they point out that when a child first becomes allergic to tuberculin that is, within three to seven weeks after the infection occurs, there may be a period of one or two weeks when the body temperature is elevated. However, this promptly subsides and thereafter fever is not found to be due to primary tuberculosis. The red cell sedimentation rate is also elevated during the febrile period and usually continues so for a few weeks after the temperature is normal.

If fever, loss of weight and other symptoms subsequently occurred and were found to be due to tuberculosis they were always caused by the reinfection phase of the disease. However, this developed with extreme rarity in the lungs during the period of childhood. Reinfection types of extrapulmonary tuberculosis, particularly involvement of the bones and joints was more often experienced during this period. Therefore the authors believe that a child who has just become allergic to tuberculin and has a brief febrile period should be on strict bed rest as long as fever is present and the red cell sedimentation rate is accelerated. At the end of this time, unless the disease enters the reinfection phase there is no objection to the child resuming school work and leading an essentially normal life for children of that age. However, as the period of adolescence approaches, all children with primary tuberculosis should be examined at least annually for the appearance of the reinfection type of disease in the lungs. Moreover, all such children should be guarded carefully against exposure to contagious cases of tuberculosis, as this is one of the diseases from which the human body does not develop dependable immunity.

LONG CONTINUED EXPOSURE TO ROENTGEN RAYS

To the Editor—We examine by fluoroscope between 40 and 50 patients twice weekly. Only the operator wears lead lined gloves and apron. The current is 70 kilovolts and 5 milliamperes. Each patient is before the fluoroscope only a few seconds preceding his refill of pneumothorax or pneumoperitoneum. The attending doctors are grouped before the fluoroscopic screen without apron or gloves. What effect will the rays have on the physicians so grouped if this is continued over a period of months and years?

M D, California

ANSWER—Such a question can be answered accurately only when an accurate determination of the exposure is made. The tolerance dose for continued exposure has been estimated at 1 roentgen per week and more recently at 0.1 roentgen per day. Reference is made to the book Medical Physics by Otto Glasser page 1382 and National Bureau of Standards Handbook 20.

DIAGNOSIS OF HERNIATION OF NUCLEUS PULPOSUS IN LUMBAR SPINE

To the Editor—Two soldiers who were discharged from the Army because of sciatica and backache did not bend over in the usual fashion when picking up their shoes and lacing them. They stood on the good leg with the trunk erect and bent the affected lower extremity in the hip and the knee to reach the foot with the hands. This relieved the tension of the sciatic nerve. Both these men were suspended by their hands holding on to the top part of a door so that their feet did not touch the floor. In this position I tapped their lumbar regions with my fist. This tapotement did not elicit any pain. When they stood on their feet tapotement of the lumbar region did elicit pain. That this can be considered one of the tests for the establishment of the diagnosis I believe is reasonable because the suspension of the body by the hands of the patient causes the weight of the section of the body below the sacrolumbar articulation to exert a pull which is sufficient to cause the herniated portion of the nucleus pulposus to retract so much that for the moment there is no pressure exerted on the spinal nerve roots which ordinarily causes the symptoms of sciatica. These diagnostic signs may not be new. However I have not seen them in the literature and therefore submit them.

RECONDITIONING IN CHEST SURGERY

COLONEL JOHN B GROW

MAJOR OMER M RAINES

AND

MAJOR ORA L HUDDLESTON

MEDICAL CORPS, ARMY OF THE UNITED STATES

One of the major developments in the field of surgery during the present war has been the general recognition of the value of a reconditioning program. The term "reconditioning program" is a broad one and covers the care of the patient from the time of his operation until he is physically fit to return to his organization. The goal of this program may be simply stated as the restoration of the patient to a normal physical and mental state of health. In order to achieve this objective it has been found necessary to have a well ordered program, which includes four important elements: (1) physical reconditioning, (2) educational reconditioning, (3) occupational therapy and (4) recreation. To be successful this program must be initiated as early in the convalescent period as possible and requires the close cooperation between the surgeon, the physical therapist, the occupational therapist and the physician in charge of reconditioning. It is our purpose in this communication not to discuss reconditioning in general but to describe experiences with a reconditioning program as applied to the specific problem of chest surgery patients during a period of approximately twenty-one months. The subjects of diversional and recreational programs and mental rehabilitation in the convalescent care of patients have been adequately discussed elsewhere. For this reason the present communication will be confined solely to the physical reconditioning of chest surgery patients.

The problems to be overcome in the physical reconditioning of the patient convalescing from a surgical disease of the chest are (1) a lowered vital capacity, (2) a decrease in stamina and strength incident to a protracted debilitating illness, (3) postural defects and (4) the loss of power of large muscle groups incident to extensive muscle cutting incisions. The other phases of reconditioning, educational reconditioning, occupational therapy and recreational and diversional activities are fully as important in this type of patient as in other groups, owing to the usual history of long standing disease with its attendant depression of morale.

The surgical diseases of the chest will be considered from the standpoint of reconditioning in the following groups: (1) tuberculosis, including pulmonary tuberculosis and tuberculosis of the pleura, (2) the suppurative diseases of the lungs and pleura, not including the bronchi, acute and chronic empyema, and lung abscess not associated with bronchiectasis, (3) conditions which

require pulmonary resection in their treatment, i. e. bronchiectasis, tumors, benign and malignant, of the lung, (4) a miscellaneous group of benign cysts and tumors of the mediastinum and pleura which require thoracotomy in their surgical treatment.

TUBERCULOSIS

The rehabilitation of the tuberculous patient is a long term program, which, owing to the nature of the disease, must be carried out under the supervision of a phthisio-therapist. Many excellent programs, initiated by local and national groups, are in operation to rehabilitate the tuberculous, and many of these patients have been restored to active and useful lives. However, the disability incident to clinical tuberculosis is not compatible with military service, and for this reason most physical reconditioning and rehabilitation activities will take place following discharge from the army. The very important educational, occupational therapy and recreational aspects of reconditioning that do apply to the period of military hospitalization are beyond the scope of this paper.

SUPPURATIVE DISEASE OF PLEURA AND PULMONARY PARENCHYMA

From the standpoint of reconditioning, we have found it convenient to group the cases of empyema and lung abscess not associated with bronchiectasis together. Acute empyemas are managed at Fitzsimons General Hospital by repeated aspiration until the presence of thick pus indicates that the empyema cavity has become localized and pleural adhesions are present. Then an adequate open drainage is done. Chronic empyemas are treated by revising drainage sinuses to secure adequate drainage and, when chronicity with cessation of obliteration of the empyema cavities occurs, a thoracoplasty with unroofing of the cavity is done. Lung abscesses are given chemotherapy and treated with bronchoscopic aspiration until evidence of failure of resolution is obtained, when open drainage, either in one or in two stages, is established. All patients in this group are transferred to a reconditioning service as soon as they have been afebrile for a sufficient period to take part in the program. This usually requires from ten days to two weeks. The patients are returned to the chest surgery wards daily for dressings but otherwise spend all their time in the reconditioning program. Here the patients' activities are graded carefully in order to avoid overdoing and to stay within the patient's limit of fatigue. He is removed from the hospital atmosphere, placed in an atmosphere of military discipline, wears a duty uniform and engages in graded army training activities.

As the patient's condition permits, breathing exercises, calisthenics and outdoor drills and marches are engaged in. Vigorous physical activity has been found

Continued dilation of the pupil is potentially hazardous. Continued dilation of the pupil may not do harm, but there is always the possibility that the dilated pupil will precipitate an attack of acute glaucoma and then irreparable damage is done. There is no need to run this risk.

URTICARIA AND ANGIONEUROTIC EDEMA

To the Editor—A woman physician aged 35 who had never before been seriously ill was taken sick three weeks ago first with nausea headache and severe vomiting. Twenty four hours later she broke out with hives of tremendous size at first only on the body later covering the arms and legs. At the same time angioneurotic edema of the eyelids lips hands and feet developed. These attacks come four or five times daily and are much worse during the night. Her condition is getting worse in spite of different treatments. No relief is obtained from local applications except that rubbing alcohol relieves the itching somewhat. She takes one tablet of $\frac{3}{8}$ grain (24 mg) of ephedrine hydrochloride four or five times daily and in addition is given injections two or three times daily of epinephrine 1:1000 0.5 cc each time or epinephrine in oil. That medication gives relief for about four hours. On advice of a skin specialist she was put on a diet which is free of meat eggs wheat coffee and fresh fruit. In the first week nicotinic acid and Calcium tablets were tried, with no results. In the second week Torantil tablets (3 x 2) were continued with the Calcium tablet. Finally Hapamin (Parke, Davis) is being tried. No relief has been obtained so far. Her general health is good, there are no other symptoms or findings. What other treatment could be tried? Can the prolonged use of ephedrine in such a great amount be harmful? The skin specialist advised against any skin tests assuming that we might get a number of wrong reactions because of the great irritability of her skin.

M D New York

ANSWER—Urticaria and angioneurotic edema occur frequently, separately or together. They are usually due to ingestion of certain foods or drugs, occasionally they seem to be associated with bacterial infection especially in the gallbladder. Skin tests in these two conditions are usually of little if any value because positive tests are often found which have no clinical relation to the cause of symptoms, and in other cases tests are negative to foods known to cause the swellings. It is known, for example, that strawberries, a frequent cause of urticaria, give an extract which usually shows negative skin tests even in susceptible persons. Benson has shown that such patients can safely eat strawberries if the berries are carefully washed in a colander with hot water. Evidently the allergen can be washed away and is not in the berry itself.

Experience has shown that most patients with urticaria and angioneurotic edema recover more or less rapidly if they avoid (1) drugs and medicines of all kinds, (2) pork including ham bacon lard and Jello (3) fresh fruits, including juices, (4) fresh vegetables, including juices, (5) peas, beans and tomatoes, cooked or raw (6) chocolate and cocoa (7) fish of all kinds (8) nuts and (9) cola drinks. This diet should be maintained for about two weeks, if symptoms subside, one of these foods is to be added at intervals of four to five days, pork and peaches last of all. If the swellings continue, other elimination diets should be tried, e.g. a strict milk free diet. Epinephrine and ephedrine may be used to control large swellings, but calcium and histamine (Torantil) usually fail. A series of injections of histamine beginning with 0.10 cc of the 1:10,000 dilution occasionally gives relief. The gallbladder and other possible foci of infection should be studied in obstinate cases.

FAITH HEALING

To the Editor—Frequently I have had occasion to answer well meaning patients with regard to the faith healing of various Catholic shrines such as at St. Ann De Beaupre and at Lourdes. I find myself at a loss for concrete evidence of the psychologic aspects of such miracles. Has any scientifically controlled investigation of these phenomena ever been conducted? What are the conclusions of these investigators both pro and con? Has such an investigation ever been suppressed? I should be grateful for any information you can offer me regarding these queries.

T R Hazlerigg M D Cleveland

ANSWER—It is certain that the suggestion of cure must benefit many persons in these shrines and the advertisement of the cures must certainly make the suggestion for cure potent. On the other hand untold misery is caused to many hopeless sufferers from structural disease and degeneration by their long and useless journeys to shrines from distant places and often far off countries. One must remember that one hears of the cures the disappointed patient does not advertise his disappointment.

PSEUDOHYPERTROPHIC MUSCULAR PARALYSIS

To the Editor—Please advise as to treatment for pseudohypertrophic muscular paralysis in a boy of 6.

Samuel Marritt M D Sackets Harbor N Y

ANSWER—There is no known treatment that exerts a favorable influence on pseudohypertrophic muscular paralysis.

FIRST INFECTION TYPE OF TUBERCULOSIS IN CHILDREN

To the Editor—I have just read the book review for "The Evolution of Tuberculosis as Observed During Twenty Years at Lymanhurst Minneapolis Board of Public Welfare 1921 to 1941" published in The Journal, August 26 1944 page 1216. The statement is made in the review that, after thirteen years of observation and study it was decided that treatment of children with the first infection type of tuberculosis is of little avail either immediately or remotely. Was the inference intended that children with the first infection type with low grade fever and failure to gain weight could be permitted to go to school and otherwise lead an essentially normal life for children of that age?

H M Janney M D Ashland Ky

ANSWER—The authors of "The Evolution of Tuberculosis as Observed During Twenty Years at Lymanhurst" state that in their experience low grade fever and failure to gain weight were not found to be manifestations of the first infection type of tuberculosis. They originally had a hospital division where such children were kept strictly in bed and under close medical observation. The symptoms mentioned, as well as others, were invariably found to be due to nontuberculous conditions, such as foci of infection in the nose, mouth and throat. However, they point out that when a child first becomes allergic to tuberculin that is, within three to seven weeks after the infection occurs there may be a period of one or two weeks when the body temperature is elevated. However, this promptly subsides and thereafter fever is not found to be due to primary tuberculosis. The red cell sedimentation rate is also elevated during the febrile period and usually continues so for a few weeks after the temperature is normal.

If fever, loss of weight and other symptoms subsequently occurred and were found to be due to tuberculosis they were always caused by the reinfection phase of the disease. However, this developed with extreme rarity in the lungs during the period of childhood. Reinfection types of extrapulmonary tuberculosis, particularly involvement of the bones and joints was more often experienced during this period. Therefore the authors believe that a child who has just become allergic to tuberculin and has a brief febrile period should be on strict bed rest as long as fever is present and the red cell sedimentation rate is accelerated. At the end of this time, unless the disease enters the reinfection phase there is no objection to the child resuming school work and leading an essentially normal life for children of that age. However, as the period of adolescence approaches, all children with primary tuberculosis should be examined at least annually for the appearance of the reinfection type of disease in the lungs. Moreover, all such children should be guarded carefully against exposure to contagious cases of tuberculosis, as this is one of the diseases from which the human body does not develop dependable immunity.

LONG CONTINUED EXPOSURE TO ROENTGEN RAYS

To the Editor—We examine by fluoroscope between 40 and 50 patients twice weekly. Only the operator wears lead lined gloves and apron. The current is 70 kilovolts and 5 milliamperes. Each patient is before the fluoroscope only a few seconds preceding his refill of pneumothorax or pneumoperitoneum. The attending doctors are grouped before the fluoroscopic screen without apron or gloves. What effect will the rays have on the physicians so grouped if this is continued over a period of months and years?

M D California

ANSWER—Such a question can be answered accurately only when an accurate determination of the exposure is made. The tolerance dose for continued exposure has been estimated at 1 roentgen per week and more recently at 0.1 roentgen per day. Reference is made to the book Medical Physics by Otto Glasser page 1382, and National Bureau of Standards Handbook 20.

DIAGNOSIS OF HERNIATION OF NUCLEUS PULPOSUS IN LUMBAR SPINE

To the Editor—Two soldiers who were discharged from the Army because of sciatica and backache did not bend over in the usual fashion when picking up their shoes and lacing them. They stood on the good leg with the trunk erect and bent the affected lower extremity in the hip and the knee to reach the foot with the hands. This relieved the tension of the sciatic nerve. Both these men were suspended by their hands holding on to the top part of a door so that their feet did not touch the floor. In this position I tapped their lumbar regions with my fist. This tapotement did not elicit any pain. When they stood on their feet tapotement of the lumbar region did elicit pain. That this can be considered one of the tests for the establishment of the diagnosis I believe is reasonable because the suspension of the body by the hands of the patient causes the weight of the section of the body below the sacrolumbar articulation to exert a pull which is sufficient to cause the herniated portion of the nucleus pulposus to retract so much that for the moment there is no pressure exerted on the spinal nerve roots which ordinarily causes the symptoms of sciatica. These diagnostic signs may not be new. However I have not seen them in the literature and therefore submit them.

RECONDITIONING IN CHEST SURGERY

COLONEL JOHN B GROW

MAJOR OMER M RAINES

AND

MAJOR ORA L HUDDLESTON

MEDICAL CORPS, ARMY OF THE UNITED STATES

One of the major developments in the field of surgery during the present war has been the general recognition of the value of a reconditioning program. The term "reconditioning program" is a broad one and covers the care of the patient from the time of his operation until he is physically fit to return to his organization. The goal of this program may be simply stated as the restoration of the patient to a normal physical and mental state of health. In order to achieve this objective it has been found necessary to have a well ordered program, which includes four important elements: (1) physical reconditioning, (2) educational reconditioning, (3) occupational therapy and (4) recreation. To be successful this program must be initiated as early in the convalescent period as possible and requires the close cooperation between the surgeon, the physical therapist, the occupational therapist and the physician in charge of reconditioning. It is our purpose in this communication not to discuss reconditioning in general but to describe experiences with a reconditioning program as applied to the specific problem of chest surgery patients during a period of approximately twenty-one months. The subjects of diversional and recreational programs and mental rehabilitation in the convalescent care of patients have been adequately discussed elsewhere. For this reason the present communication will be confined solely to the physical reconditioning of chest surgery patients.

The problems to be overcome in the physical reconditioning of the patient convalescing from a surgical disease of the chest are (1) a lowered vital capacity, (2) a decrease in stamina and strength incident to a protracted debilitating illness, (3) postural defects and (4) the loss of power of large muscle groups incident to extensive muscle cutting incisions. The other phases of reconditioning, educational reconditioning, occupational therapy and recreational and diversional activities are fully as important in this type of patient as in other groups, owing to the usual history of long standing disease with its attendant depression of morale.

The surgical diseases of the chest will be considered from the standpoint of reconditioning in the following groups: (1) tuberculosis, including pulmonary tuberculosis and tuberculosis of the pleura, (2) the suppurative diseases of the lungs and pleura, not including the bronchi, acute and chronic empyema and lung abscess not associated with bronchiectasis, (3) conditions which

require pulmonary resection in their treatment, (4) bronchiectasis, tumors, benign and malignant, of the lung, (5) a miscellaneous group of benign cysts and tumors of the mediastinum and pleura which require thoracotomy in their surgical treatment.

TUBERCULOSIS

The rehabilitation of the tuberculous patient is a long term program, which, owing to the nature of the disease, must be carried out under the supervision of a physiotherapist. Many excellent programs, initiated by local and national groups, are in operation to rehabilitate the tuberculous, and many of these patients have been restored to active and useful lives. However, the disability incident to clinical tuberculosis is not compatible with military service, and for this reason most physical reconditioning and rehabilitation activities will take place following discharge from the army. The very important educational, occupational therapy and recreational aspects of reconditioning that do apply to the period of military hospitalization are beyond the scope of this paper.

SUPPURATIVE DISEASE OF PLEURA AND PULMONARY PARENCHYMA

From the standpoint of reconditioning, we have found it convenient to group the cases of empyema and lung abscess not associated with bronchiectasis together. Acute empyemas are managed at Fitzsimons General Hospital by repeated aspiration until the presence of thick pus indicates that the empyema cavity has become localized and pleural adhesions are present. Then an adequate open drainage is done. Chronic empyemas are treated by revising drainage sinuses to secure adequate drainage and, when chronicity with cessation of obliteration of the empyema cavities occurs, a thoracoplasty with unroofing of the cavity is done. Lung abscesses are given chemotherapy and treated with bronchoscopic aspiration until evidence of failure of resolution is obtained, when open drainage, either in one or in two stages, is established. All patients in this group are transferred to a reconditioning service as soon as they have been afebrile for a sufficient period to take part in the program. This usually requires from ten days to two weeks. The patients are returned to the chest surgery wards daily for dressings but otherwise spend all their time in the reconditioning program. Here the patients' activities are graded carefully in order to avoid overdoing and to stay within the patient's limit of fatigue. He is removed from the hospital atmosphere, placed in an atmosphere of military discipline, wears a duty uniform and engages in graded army training activities.

As the patient's condition permits, breathing exercises, calisthenics and outdoor drills and marches are engaged in. Vigorous physical activity has been found

to be of definite benefit in hastening the obliteration of empyema and lung abscess cavities. The usual experience is that by the time the empyema or lung abscess cavity has disappeared the patient has been restored to his normal weight, stamina and strength. He may then be returned to full military service with his organization. Chronic empyemas which require thoracoplasty of an extensive nature in their treatment frequently incapacitate the soldier for further military service through the deformity incident to the surgical procedure and the consequent reduction in vital capacity.

PULMONARY RESECTION

The reconditioning of patients following pulmonary resection may be divided roughly into three stages: (1) the immediate convalescent care, (2) the physical therapy period comprising the period from the seventh postoperative day to the twenty-first postoperative day, and (3) the period from the twenty-first postoperative day to the time of his discharge from the hospital, when he is a patient in the reconditioning service. If there is no associated suppurative sinus disease, patients who have had resection of no more than the amount of pulmonary tissue contained in the middle and lower lobes of the right lung may be returned to military duty. Patients who have had more pulmonary tissue resected than this amount are usually incapacitated for military service.

In cases involving the partial resection of one lung, two drainage tubes are left in the intercostal spaces just above the diaphragm, one anteriorly and one posteriorly. These tubes are connected to underwater sealed empyema bottles. The intercostal drainage tubes are usually removed on the third or fourth postoperative day. Other measures during this period are those designed to prevent the development of atelectasis.

The seventh to the twenty-first postoperative days fall into the physical therapy period. During this time breathing exercises and shoulder exercises are started while the patient is still confined to the ward. The shoulder exercises consist of moving the arm through a complete range of motion supplemented by repeated passive exercises. Later these are changed to active assistive exercises and active exercises of the shoulder girdle. The shoulder exercises are unilateral and confined to the operative side. Breathing exercises are bilateral and symmetrical and involve the contractions of the accessory respiratory muscles as well as the regular inspiratory and expiratory muscles during strong, forced breathing. The purpose of the breathing exercises is to increase the vital capacity. The purpose of the shoulder exercises is to prevent contraction and limitation of range of motion of the shoulder joint. Usually exercises are given twice daily. When the patient becomes ambulatory during the second and third postoperative weeks, the treatments are given in the Physical Therapy Clinic. When muscle soreness, rigidity or limitation of motion are present, additional treatment consists of radiant heat or hot packs to the involved muscle group prior to the administration of the exercises. Air cooled general ultraviolet light irradiation is given to stimulate immunity reactions and increase the patient's general strength.

After the third postoperative week the patient's convalescence is sufficiently advanced that he may be transferred to the Reconditioning Service. Here his program is much as it has been outlined for the patients with suppurative disease of the lung parenchyma and

pleura. The exercises concentrate in increasing the vital capacity and restoring the strength of the shoulder girdle. The men are trained in the use of and encouraged to engage in activities with Indian clubs, rowing machines, pulley weights, dumb-bell exercises, straddle pull ups, push ups, chin ups and resistive exercises. For patients who have no draining sinuses swimming has been found to be important, from the standpoint both of recreation and of physical conditioning. The Australian crawl swimming stroke is particularly useful in loosening up the muscles of the shoulder girdle. Of 31 patients treated in this manner during the past year who required the resection of no more than the amount of pulmonary tissue contained in the middle and lower lobes of the right lung 25 were returned to duty, the average length of hospitalization after operation being approximately ten weeks. Of the remaining 6 who were discharged 3 were discharged because of suppurative sinus disease and suppurative bronchitis of the remaining lung, and 3 were discharged for reasons not related to the condition for which resection was performed.

EXPLORATORY THORACOTOMY

Patients who require exploratory thoracotomy, such as the removal of benign cysts, tumors of the pleura and mediastinum and the repair of diaphragmatic hernias, usually have but little respiratory difficulty as a residual of the operation. The primary problem in these patients is the restoration of stamina and strength with recovery of function of the shoulder girdle. They follow the same routine as given under "Pulmonary Resection." The results in this group are uniformly good.

COMMENT

Unfortunately it is not possible to compare the results obtained before and after the initiation of the reconditioning program at this hospital, owing to the fact that the cases are not comparable and surgical techniques have been changed during this period. However, the rapid response of this group of patients to the program, the excellent physical conditioning obtained and the high percentage of cases returned to military duty have been striking. This is illustrated by the fact that during this period of 31 cases treated by the resection of no more than the amount of pulmonary tissue contained in the middle and lower lobes of the right lung 25 were returned to duty with an average of ten weeks of hospitalization following surgery. Of the remaining 6 who were discharged 3 were discharged for suppurative sinus disease with suppurative bronchitis in the remaining lung tissue. Three were discharged for diagnoses unrelated to the disease for which pulmonary resection was performed. Twenty-two soldiers with chronic non-tuberculous empyema completed treatment during this period. Of this number 18 were returned to duty and 4 were discharged from the service. The reconditioning program was of the greatest value in this group, requiring prolonged hospitalization by maintaining general physical fitness and a high morale.

CONCLUSIONS

1 A planned reconditioning program contributes greatly to the success in the management of chest surgery patients.

2 A satisfactory reconditioning program requires close cooperation between the surgeon, the physical therapist, the occupational therapist and the medical officer in charge of reconditioning.

PERSISTENCE OF VIRUS EXCRETION
IN THE STOOLS OF POLIO-
MYELITIS PATIENTS

DOROTHY M HORSTMANN, M.D

ROBERT WARD, M.D

AND

JOSEPH L MELNICK, PH.D

NEW HAVEN, CONN

It is now an established fact that many patients with acute poliomyelitis excrete virus in their stools, but little is known of the duration of excretion of virus in fecal material beyond the first four weeks of the disease. The literature up to 1940 has been summarized in two papers by Vignec, Paul and Trask.¹ An example of long persistence of the virus was reported in 1939 by Lepine and his associates,² who demonstrated it in the stools of a child forty-one, seventy-four and possibly one hundred and twenty-three days after the abortive disease. Since 1940 two late isolations have been reported: one by Howitt, Buss and Shaffrath³ fifty days and another by Wenner and Casey⁴ forty-five days after the onset of poliomyelitis. Piszczek and his associates⁵ recovered virus from the stools of a healthy contact who had been exposed one and two months before the specimen was collected.

The present study was undertaken to determine the average duration of excretion of virus in stools of patients following acute infection and to ascertain whether a chronic carrier state similar to that occurring in typhoid exists in poliomyelitis.

MATERIALS AND METHODS

Sixty patients who were admitted to the New Haven Hospital during the summer epidemic of 1943 and 1 who entered in February 1944 were selected for study. In all of these a clinical diagnosis of poliomyelitis had been established. There were 46 cases of the paralytic and 15 of the nonparalytic type. An attempt was made to collect specimens during the first or second week of the disease and at four to six week intervals thereafter. All the materials were frozen immediately or within a few hours after collection and stored on solid carbon dioxide until ready to be tested.

The technic of preparation of materials for inoculation was that developed by Melnick,⁶ with a few minor changes. The stools were for the most part 35 to 50 Gm in amount, although some were as small as 10 Gm. In all specimens the inoculum was prepared by ultracentrifugation at 39,000 revolutions per minute. Immature rhesus monkeys (*Macaca mulatta*) were used as test animals throughout. Eighty-four monkeys were used, and of these 57 were used more than once. Inocu-

lations were by the intracerebral route in fifty-four tests and directly into the lumbar cord in eighty and by a combination of the two routes in twelve. All but 2 monkeys were ultimately killed and a test was considered positive when microscopic lesions characteristic of poliomyelitis, viz neuronal necrosis, neuronophagia and perivascular cellular infiltration were seen in the spinal cord. The 2 monkeys not killed exhibited typical paralytic poliomyelitis and were preserved for use later. These also were considered to represent positive tests.

RESULTS

Of the 146 tests performed on 123 specimens 28 were positive, 91 negative and 4 incomplete because of premature death of the test animal. The chart gives the time distribution of the positive tests among the 119 specimens on which complete tests were carried out.

By this method 50 to 60 per cent of the patients were found to excrete virus in the first four weeks of the disease. The rate then falls off steadily, although at five to six weeks 27 per cent of the specimens tested were positive and at seven to eight weeks 12.5 per cent. Between the ninth and twenty-fourth weeks only 1 of 52 specimens tested was shown to contain virus, this was the latest positive obtained and came from a boy 8 years old in the twelfth week of paralytic disease.

Excretion of virus in 119 stools of 61 poliomyelitis patients

It has been emphasized previously that the stools of young children under 8⁸ and particularly children with nonparalytic disease are more apt to contain virus than do those of older children, as a result the younger child has been suspected of being the more frequent and important carrier. In the present study no difference was detected in the number of positive specimens from the younger and older age groups in either the acute or the convalescent period, nor was there any difference between the paralytic and nonparalytic patients as to virus excretion. This may be due to the method employed.

COMMENT

The prevalent concept of the virus excretion after poliomyelitis is that stools commonly contain the agent for three to four weeks following the onset but rarely thereafter. The results of this study indicate that the period of virus excretion is longer and extends into the seventh and eighth weeks in an appreciable percentage of cases.

It provides no evidence for the existence of persistent carriers of poliomyelitis virus but it is possible that failure to demonstrate such carriers was due to the relatively small number of subjects studied.

7 Results of comparison of the two techniques to be published.

It should be emphasized at this point that these results are relative and are dependent on the method employed. If a cruder method, such as that which has been employed in certain community surveys, had been used, no doubt the excretion rate would have been found to be less than is here reported.

An attempt is not made to interpret the epidemiologic significance of the findings but rather to record the observations.

SUMMARY

1 The duration of excretion of poliomyelitis virus in the stools of 61 patients was studied. It was found that 61 per cent excrete virus during the first two weeks after onset of the disease, 50 per cent during the third and fourth weeks, 27 per cent at the fifth and sixth weeks, 12.5 per cent at the seventh and eighth weeks. Between the ninth and twenty-fourth weeks virus was detected in only 1 of 52 specimens tested; one excreted in the twelfth week.

2 Not one of the 61 patients followed was demonstrated to become a persistent carrier of poliomyelitis virus.

PNEUMOCOCCIC ARTHRITIS

REPORT OF CASE OF SO-CALLED PRIMARY PNEUMOCOCCIC ARTHRITIS

WILLIAM P. BOGER, M.D.

BLUEFIELD, W. VA.

All writers agree that pneumococcic arthritis is a rare disease, and the discussion of the disease is in most instances limited to the making of this observation. This is true in the eight reviews of "rheumatism and arthritis"¹ which cover the American and British literature for the years 1935 through 1940. These eight reviews cite only 1 case of pneumococcic arthritis, that of Instone,² and this case seems open to question on the grounds that it does not fit the clinical picture of pneumococcic arthritis and the only proof of etiology is the growth of pneumococci from a throat swab.

The literature of pneumococcic arthritis consists of a series of case reports, and it is of interest to note that several of the best reviews of the subject have been prompted by the observations of single cases.³ The fact that few observers have seen more than 1 case and recorded cases are so few makes it seem doubtful if any one can speak with authority concerning the disease.

Pneumococcic arthritis should be regarded as a manifestation of a septicemia even in those cases in which

the primary focus from which the organisms gained access to the blood stream cannot be demonstrated. With this concept of the disease I present a case of so-called "primary" or "cryptogenic" pneumococcic arthritis in which no infection apart from the knee could be demonstrated.

REPORT OF CASE

N. F., a Negro woman aged 50, was referred to the hospital because of "phlebitis, arthritis and anemia." On Oct. 29, 1942, she was well and sitting in a rocking chair on a neighbor's porch when she was seized with a sudden acute pain in the back of the left knee. The pain was severe and prevented the patient from walking home. Massage and the application of liniments and heat failed to alleviate the pain. The following day the knee was swollen and painful on motion. A doctor was summoned, and "pills and liniment" were prescribed without benefit. During the succeeding days the knee became more swollen and painful and the patient felt "chilly" and "knew" she had fever.

November 7, on the tenth day of her complaint, the patient presented herself for admission to the hospital. The patient's past health had been excellent, she could not recall having been sick for many years, and specific questioning relative to colds, pneumonia, pleurisy, running ears, "gum-boils" and genital infections failed to reveal any such infections.

Examination showed that the patient was well developed and nourished. She lay in bed complaining bitterly of a painful and much swollen left knee, which was held in semi-flexion. She complained of nothing except her knee and appeared to be in good general condition. The temperature was 103 F., pulse rate 100, respiratory rate 25. There were few teeth remaining in the patient's mouth and these were carious, but the gums were in good condition and there was no pyorrhea. The chest was symmetrical and moved equally with respiration, no rales were heard. The blood pressure was 125/85, the heart was normal in size, rate and rhythm, and no murmurs or thrills were demonstrated. The abdomen was nontender and no masses could be felt, the spleen was specifically sought for but not found. Pelvic examination was not done because of pain in the leg. No lymphadenopathy was present.

The left leg was swollen from the hip to the ankle and was easily twice the size of the right leg. The size of the leg was due largely to pitting edema limited to the posterior (dependent) aspect of the leg from the left hip to the ankle. Large, engorged veins coursed over the patellar and lateral aspects of the knee, and the dull purplish discoloration which passes for "redness" in the colored race was apparent over the region of the knee and lower thigh. The knee joint was much swollen by an effusion, the patella was ballotable, and the joint was both tender and "hot" to touch. Movement was painful and limited both by the pain and by the size of the effusion into the joint. Fluctuation just proximal and medial to the patella suggested suppuration in the soft tissues. There was no lymphadenopathy in the left groin despite the obvious signs of inflammation around the knee.

X-ray examination revealed soft tissue swelling but no evidence of pathologic changes in the bone. There was some lifting of the patella. The diagnosis of acute septic arthritis was made, and aspiration of the joint was done under aseptic conditions. An 18 gage needle was used and it was frequently clogged by definite clots of purulent matter during the withdrawal of 310 cc of thick, yellowish green pus. This amount of pus was readily obtained and there was no reason to doubt that it was obtained directly from the knee joint. Examination of the pus revealed countless numbers of both intracellular and extracellular gram positive diplococci, which proved to be type XII pneumococci in pure culture.

Sulfadiazine was given in full dosage, 3 Gm initially and 1 Gm every four hours thereafter for twenty-two days. The blood level of sulfadiazine was checked every other day, and a level between 9.5 and 15.8 mg per hundred cubic centimeters was maintained.

The patient's temperature, which was 103 F. at the beginning of her disease, subsided by the fifth day of therapy and there-

after never rose above 99.6 F. Appetite was sustained throughout the hospital stay, and the general good condition of the patient was remarked by all.

Morphine $\frac{1}{4}$ and $\frac{1}{4}$ grain (11 and 16 mg) was required for the relief of pain, and light plaster of paris splints were used to immobilize the painful joint. Despite some pain, the limb was removed from the splints once a day and the knee moved through as full a range of motion as possible.

On November 13 a second aspiration was done and 340 cc of the same type of pus as previously noted was removed. Five Gm of sodium sulfadiazine dissolved in 100 cc of distilled water was injected into the joint. This pus that was withdrawn from the joint after five days of adequate sulfadiazine therapy gave a pure growth of type XII pneumococci. Aspiration of the joint was repeated on the 16th, 19th and 20th, but no organisms were found in the material withdrawn. On November 24 a swelling was found in the left mid thigh that presented all the cardinal signs of inflammation. Aspiration at this site yielded 240 cc of greenish purulent material which was sterile on culture.

X ray films taken during the hospital course failed to reveal any bone destruction in the knee joint. Blood counts done every third day showed a hypochromic anemia of moderate severity, hemoglobin values averaged 58 per cent (Sahli) and the red counts averaged 3,410,000. One 500 cc transfusion was given, which did not change the count materially. The high white cell count obtained was 12,200 and all other counts averaged 7,460. The differential counts at no time showed more than 76 per cent polymorphonuclear leukocytes.

Six blood cultures failed to yield a growth despite precautions to inhibit the sulfadiazine in the blood samples. Throat cultures were negative for pneumococci, and so also were cultures of scrapings from the carious teeth.

The patient was discharged on Nov 29, 1942 with a knee joint that did not pain her, and she was able to walk without discomfort, the knee could be extended to 170 degrees and flexed to 80 degrees giving her an effective range of motion of 90 degrees.

INCIDENCE

Weichselbaum⁴ described the first case of pneumococcic arthritis and since then cases have been infrequently reported. In table 1 the number of cases of pneumococcic arthritis listed is 227, an addition of 42 cases to the compilation of Plisson and Brousse,⁵ but

there are undoubtedly additional cases which have not come to my attention.

Pneumococcic arthritis is said to occur as a complication of pneumonia in 0.1 per cent of the cases.⁶ This often quoted incidence was determined by Herrick⁷ and has never been revised. In table 2 I have presented Herrick's data and other more recent studies. The incidence of arthritis as a complication of pneumonia would appear to be 0.3 per cent.

CLASSIFICATION OF PNEUMOCOCCIC ARTHRITIS

Since 70 to 75 per cent of the pneumococcic arthritis cases occur in association with pneumonia,⁸ efforts have been made to classify them as preceding, following or occurring with a pneumonia. Certain cases, however, have been clearly shown to be completely independent of pneumonia, thus supporting the original dictum⁴ that *Diplococcus pneumoniae* can cause not alone pneumonia but also various other processes, either at the same time as pneumonia or entirely independent of it. The most inclusive classification is⁵

- 1 Arthritis evolving before, during or after a pneumonia
- 2 Arthritis evolving without pneumonia but before, during or after an extrapulmonary infection (meningitis, pericarditis, endocarditis, otitis, peritonitis, cystitis, pharyngitis)
- 3 Arthritis evolving without any other acute manifestation due to the pneumococcus (primary or cryptogenic arthritis)

Plisson and Brousse⁵ found 26 cases of "primary" arthritis, 14 cases in children and 12 in adults, but no bibliography was presented. Bulkley⁹ found 48 cases of pneumococcic arthritis occurring without pneumonia, but in 18 of these cases an extrapulmonary pneumo-

coccic infection was found (pyosalpinx, umbilical fistula, tonsillitis, pharyngitis, otitis media, labor, peritonitis and cystitis). The remaining 30 cases which were regarded as "primary" were the 26 previously listed by Plisson and Brousse⁵ and 4 cases of his own about which no particulars are given.

The only cases occurring apart from pneumonia concerning which I have been able to gather any particulars are the following. Widal and Meslay¹⁰ reported a male of unknown age with involvement of the left metacarpophalangeal joint who died and was shown to have pneumococcic pericarditis. Widal and Lesne¹¹ had a man aged 68 who recovered after involvement of the left sternoclavicular joint and the small joints of the left hand. Griffon¹² stated that a woman aged 71 whose right ankle was incised and drained, died and necropsy showed pneumococcic meningitis and vegetative endocarditis. Allen and Lull¹³ cultured pneumococci from the knee of a woman aged 40 who died. Billings and Preble¹⁴ had a woman aged 43 with involvement of the elbow, knee, wrist and ankle who died and was shown to have pneumococcic pericarditis and meningitis. Plisson and Brousse⁵ saw a colonial soldier of unstated age whose left knee was involved by pneumococcic arthritis and who recovered. Bloomberg¹⁵ cultured pneumococci from the metatarsophalangeal joint of a Negro aged 27 who recovered. Of these 7 cases occurring apart from pneumonia only 3 can really be called "primary" or "cryptogenic," and recovery occurred in these 3 cases together with my own case.

SYMPTOMS AND CLINICAL FEATURES

Pneumococcic arthritis is a septic arthritis, and it is the feeling of some that there are no signs and symptoms which distinguish it from other varieties.¹⁶ Pain is always present but may be gradual or sudden in onset, swelling may be slight and involve only the joint, or an intense inflammatory edema may extend to the entire limb; the local signs of acute inflammation are well defined and local tenderness is great. Large effusions are common and it is not at all unusual for infection to spread to the periarticular structures with destruction of ligaments and extension of suppuration into the musculature surrounding the joint. The temperature usually ranges between 102 and 103 F.

It is of interest that Chantemesse, Macaigne and Chipault¹ regarded several clinical features as almost pathognomonic, all of which were noted in my case: white, periarticular edema with prominent venous collateral circulation, elevated temperature with the patient in good general condition, the absence of regional lymph gland reaction, and the rapidity of reappearance of swelling of the joint after aspiration.

According to Bulkley,⁹ pneumococcic arthritis is monarticular in about 75 per cent of the cases, and

arthritis has been noted in every joint except the acromioclavicular joint and the joints of the vertebral column. In this connection the case of Milch¹⁸ may be mentioned, for he isolated a type II pneumococcus from an abscess of the vertebral column but in this case there was some question of Pott's disease.

BACTERIOLOGY

The only proof of pneumococcic arthritis is the demonstration of pneumococci in fluid aspirated from the involved joint. An arthritis appearing during the course of pneumonia is circumstantial evidence of the arthritis being pneumococcic in origin, but Smirnow¹⁹ demonstrated typhoid bacilli, streptococci and staphylococci in 5 out of 10 cases of pyoarthrosis complicating pneumonia.

There has been some speculation about the type of pneumococcus which produces arthritis and other complications. The most extensive study of this sort has been that of Cecil and his associates²⁰ who found 8 cases of arthritis among 1,913 typed pneumonias. We were able to find only 16 cases of pneumococcic arthritis in which the type had been determined, and this number of cases does not permit the drawing of any conclusions, type I, 8, type II, 2, type III, 2, type IV, 4 (table 1).

PATHOLOGY

There is little or no information available on the microscopic pathology of pneumococcic arthritis. Cave²¹ feels that the morbid anatomy is that of any other septic joint. Keefer, Parker and Myers,²² in speaking of "pyoarthrosis" in general, say that destruction of cartilage occurs "not by direct action of bacteria but by an action of proteolytic enzymes in the leukocytes of pus to a lesser extent by pressure and synovial pannus."

The tendency of pneumococcic arthritis to perforate the joint capsule has been mentioned,²³ but "in many of the acute and most virulent forms there is no solution of continuity in the synovia or cartilage."⁷

TREATMENT

Pain in these cases is acute and may require large doses of opiates. Light plaster of paris splints give great comfort, but immobilization has been accepted as treatment only in those cases impossible of joint recovery.²⁴ Arthrotony has been recommended in the past, but comparable and even superior results are obtained by repeated aspirations. A large bore needle should be used for all observers have noted the large flakes of purulent matter which are present in the yellowish green pus withdrawn from these joints. In order to preserve joint function, passive movement should be insisted on at the earliest possible moment. Physical therapy should be instituted as soon as acute pain has subsided with the hope that wasting of muscles will be prevented and joint disability decreased. Sul-

sonamide therapy has strikingly reduced the mortality rate of pneumonia and has reduced complications commensurately, so it may be expected that these drugs will be of service in preventing pneumococcic arthritis as well as in treating it. I have seen no report of the use of penicillin in this disease. But whatever therapy is used, one's enthusiasm should be tempered by the observation of Herrick⁷ that "it is well to remember that, with serous and in a few cases even with purulent exudate, recovery has ensued either spontaneously or by the simpler measures of rest, compression or aspiration."

PROGNOSIS

Pneumococcic arthritis is said to carry a high mortality rate. Raw²⁵ had 7 patients and 3 died (42 per cent), Sever²⁶ had 6 patients and 3 died (50 per cent), Herrick⁷ gives the mortality rate as 65 per cent and Bulkley⁹ found that with multiple foci of pneumococcic infection the mortality was 72 per cent whereas when only a single joint was involved the mortality was 24 per cent.

It is my feeling that these mortality rates are not those of pneumococcic arthritis but those of pneumococcic bacteremia. The cases of isolated pneumococcic arthritis are too few to permit any one to quote a mortality rate for this condition, and I feel that it is worthy of comment that recovery occurred in all 3 cases of this sort which I found and my own case likewise.

The prognosis with respect to joint function is influenced by the patient's general condition, but one need not be pessimistic about this type of arthritis. Cave²¹ feels that there is generally permanent impairment. Bulkley⁹ found details of joint function given for only 34 patients among 172 and of these 25 had "good functioning joints" and the impression was given that the remaining 9 had useful joints. Of Raw's²⁵ 7 patients 3 had useful joints although they remained "slightly stiff." The patient of Plisson and Brousse⁵ recovered 90 degrees of flexion and my own patient was able to walk without pain and had 90 degrees of motion.

It seems fair to say that ankylosis can be prevented in a high percentage of pneumococcic arthritis cases and a useful joint result, but there will be some permanent damage in almost every joint infected by pneumococci.

COMMENT

In the understanding of bacterial diseases a transient bacteremia has been increasingly invoked as an explanation of multiple manifestations of a single infection. Bacteremia has been frequently demonstrated as one phase of pneumococcic pneumonia, and the rare complications of pneumonia, arthritis among them, are readily ascribed to this bacteremia. Similarly, when multiple pneumococcic infections exist simultaneously or in close temporal relationship, bacteremia seems an obvious link between them. Under these circumstances pneumococcic bacteremia is the fundamental disease, and only as one of the manifestations thereof completely dominates the clinical picture does there seem any reason to subordinate the importance of the bacteremia.

If pneumococcic arthritis is a clinical entity, and some have doubted that it is,²⁷ the only cases which should be considered are those in which arthritis is the sole manifestation of pneumococcic infection. Such cases are extremely rare, and it seems doubtful whether there are enough of them to justify comments on the course, prognosis and treatment of pneumococcic arthritis as a disease. It does appear to be unwarranted to ascribe such a grave prognosis and high mortality to pneumococcic arthritis as is done commonly in the literature, when examination of the cases shows that pneumococcic bacteremia far outweighs the importance of the arthritis. It seems worthy of comment that the only patients with primary pneumococcic arthritis which I found in the literature recovered.

The case which I have reported was a case of primary or cryptogenic pneumococcic arthritis and the only case of pneumococcic arthritis which I have observed. I was impressed by the clinical features which Chantemesse, Macaigne and Chipault¹⁷ called attention to, the general well-being of the patient, the edema of the involved limb, the absence of regional lymph glands, the extensive venous collateral circulation and the rapid accumulation of fluid after aspiration of the joint. If these observations are confirmed by others they may be of great clinical value in suggesting the diagnosis of pneumococcic arthritis.

I had no precedent for the injection of sodium sulfadiazine into the knee joint, but this procedure may have had a salutary effect, especially in view of the fact that viable pneumococci were aspirated from the joint after five days of adequate oral sulfadiazine therapy. No claims are made for this form of therapy, for, as Herrick⁷ has cautioned, spontaneous recoveries have been noted.

CONCLUSIONS

A case of cryptogenic pneumococcic (type XII) arthritis was observed. Forty-two cases of pneumococcic arthritis are added to the compilation of Plisson and Brousse,⁵ bringing the number of cases to 227.

The incidence of arthritis as a complication of pneumococcic pneumonia is more nearly 0.3 per cent than 0.1 per cent, the figure commonly quoted.

Those cases of pneumococcic arthritis in which arthritis is the only manifestation of disease are the only ones which merit consideration as a clinical entity and they are very rare. Pneumococcic bacteremia with arthritis as only one of the complications carries a high mortality rate, but evidence is lacking to establish a grave prognosis or high mortality for pneumococcic arthritis by itself.

Influence of Climate on Some Diseases.—The influence of climate on some diseases is beyond dispute. Certain parasites are dependent on weather both directly and indirectly through the fortunes of their insect hosts. The distribution of the insect carriers in some instances is definitely limited by temperature and humidity, and the same factors, operating on the food supply, must affect the size and distribution of animal reservoirs of infection. Climate and its emergencies have a definite influence on crowd formation and crowd movements, and perhaps on the means by which infection travels through a crowd. The evidence is not so clear as to seasonal and climatic variations in physiological resistance to infection, but it is strongly probable that they do occur.—Smith, Geddes. Plague On Us, New York, Commonwealth Fund, 1941.

AND

BENEDICT E. ABREU, Ph.D.

AUGUSTA, GA.

Mechanical methods for initiating respirations that have ceased from any cause have been the subject of frequent study and controversy. The lesser or pulmonary circulation, though intimately associated with respiration, has not been the subject of adequate study with the chest closed. An improved technic has been developed for measuring the effective pulmonary and the effective systemic blood pressure in animals with closed chest and premedicated with 3 to 5 mg. of morphine sulfate per kilogram. The pulmonary and systemic blood pressures have been recorded while respiration was maintained with each of the following resuscitators:

- 1 Anesthetic machine
- 2 Emerson respirator (iron lung)
- 3 Kreiselman infant resuscitator
- 4 Kreiselman "bellows" resuscitator
- 5 Artificial pulmonary ventilation for operating room (Mautz model)
- 6 Lung ventilator
- 7 Emerson resuscitator, J. H. model

METHODS

All operative procedures were accomplished with the aid of local infiltrations of 1 per cent procaine hydrochloride. The trachea was cannulated in all animals to insure a free airway and to prevent the possible danger of blowing air into the esophagus and stomach.

Changes in the pressure relationship between the abdominal and thoracic cavities were recorded, since they influence venous return to the heart.¹ Balloons fastened to leaden tubes were inserted into the abdominal and thoracic cavities. Subtraction of the intrathoracic pressure from the abdominal pressure was accomplished with a differential manometer² and provided measurements of the net abdominal pressure (fig. 1). Changes in this net abdominal pressure can modify venous return to the heart from the abdominal reservoirs. These changes may be the result of an increase or a decrease in intrathoracic pressure without a comparable rise or fall in intra-abdominal pressure.

The gross arterial and the gross venous pressures are those commonly measured and are the amount of pressure present over and above the atmospheric pressure.

2. Woodbury R. A., Hamilton W. F. and Torpin R. The Relationship Between Abdominal, Uterine and Arterial Pressures During Labor. *Am. J. Physiol.* 121: 640, 1938.

The net arterial and the net venous pressures are the pressures present over and above those which are surrounding the particular organ whose net pressure is being measured. The net arterial pressure to the lungs is the pulmonary arterial pressure minus the intrapleural pressure, i. e. it is the pressure distending the pulmonary arteries and against which the right heart pumps. The net coronary arterial pressure is the pressure within the coronary arterial system minus the pressure in the thorax. This net coronary pressure is acting to push the blood to the cardiac tissue. These gross and net pressures were measured by means of simple and differential manometers.³ A method to be described in detail elsewhere⁴ was developed for the measurement of these pressures from intact chests not operated on. Sounds adapted to the size of the animal, generally 12-16 Gm., were fastened to manometers (fig. 1). Isotonic solution of sodium chloride was allowed to drip slowly through these sounds to minimize the possibility of coagulation. With use of only gentle pressure one sound was inserted into the exposed left carotid artery and into the aorta and past the semilunar valves into the left ventricle. The other sound was inserted into the exposed external jugular down to the superior vena cava and right auricle and into the right ventricle.

Various degrees of reduced cardiac activity with severe depression or complete arrest of respiration were produced repeatedly by complete occlusion of the airway in 4 dogs and by the use of helium with the carbon dioxide absorption technic in 6 dogs. In some experiments only the immediate circulatory effects of the aforementioned methods of mechanical artificial respiration were studied in quick succession. This was accomplished by recording the pressure relationships during 3 to 10 cycles of each method of resuscitation. This was repeated several times with each animal, using the various types of resuscitators in different order of rotation. By producing several periods of severe hypoxia in each animal it was possible to compare the effect of several methods in each animal.

Cardiac arrest was produced (1) by complete occlusion of the airway in 3 dogs, (2) by the use of helium with the carbon dioxide absorption technic in 2 dogs and (3) by electrically induced ventricular fibrillation in 2 dogs. In these animals the pressure relationships were recorded while all of the methods of resuscitation being studied were used in rotation.

RESULTS AND COMMENT

When respiratory arrest and slow weak cardiac contractions were produced by the administration of helium, using the carbon dioxide absorption technic, recovery was accomplished with any of the mechanical methods of resuscitation studied. Irrespective of the method employed, the immediate effects on the pulmonary and systemic blood pressures of these hypoxic animals were similar. The immediate effects of the intrapulmonic positive and negative pressure type of resuscitator are illustrated in figure 2B with records obtained with the Emerson resuscitator, while those of the intrapulmonic intermittent positive pressure type of

resuscitator are illustrated in figure 2 C with records obtained with the Kreiselman "bellows." The thoracic, left ventricular and right ventricular pressures were increased during the inflation of the lungs. These increases in ventricular pressures, however, were entirely passive, since the effective net ventricular pressure showed no change during the inflation phase. Restated this means that any blood flow which was produced by the resuscitators did not reach the coronary and cerebral arteries. Instead, blood was pushed toward the extremities and cutaneous areas. The absence of any change in net ventricular pressures also means that inflation did not significantly modify the blood pressure distending either ventricle and it did not change the effective net pulmonary arterial or venous pressure. Dogs with acute cardiorespiratory failure have elevated systemic venous pressure (fig 2). This may account for the fact that 10 to 12 mm of mercury positive pressure inflating the lungs did not significantly hinder venous return. This is in agreement with the observation⁵ that increases in the intrathoracic pressure in patients with congestive heart failure did not significantly hinder venous return to the heart. It is important to emphasize, however, that intrapulmonic positive pressure above 10 to 12 mm of mercury, if maintained for prolonged periods of time, may hinder venous return to the heart. There was no evidence to substantiate the theory that resuscitators employing posi-

ventricular fibrillation (fig 3), recovery was not accomplished with any of the mechanical artificial methods of resuscitation studied. Again, irrespective of the method of resuscitation chosen, the pressure changes were not significant and were similar to those shown in figure 2. These results, however, differ from the effects of deep

Fig 2—Pressure records from dog from above downward left ventricular net left ventricular, thoracic right ventricular and net right ventricular pressures and line interrupted at two seconds intervals. Upper left tracings were obtained when respiration was normal and before production of anoxia. Upper right tracings were obtained while respiration was maintained with Emerson resuscitator and after severe anoxia had been produced by helium and carbon dioxide absorption technique. Respiratory arrest and slow weak cardiac contractions were present. Lower tracings were obtained one minute after recording the upper right tracings and while respiration was maintained with Kreiselman bellows. During the inflation phase (arrows) with the Emerson resuscitator or with the Kreiselman bellows the thoracic pressure and the right ventricular and left ventricular pressures are increased. But the effective blood pressure and the net left and net right ventricular pressures are not increased.

spontaneous breathing and dying gasps.⁴ Deep forceful breathing, even in the presence of complete cardiac arrest, repeatedly increased venous return to the right ventricle and to the pulmonary vessels and also moved some blood from the pulmonary vessels on into the left ventricle. These same changes are more pronounced

Fig 1—Diagram showing method of recording gross pressures and net pressures in unanesthetized animals with closed chests. Hollow stainless steel sounds were inserted in the left and right ventricles and balloons were placed in the thoracic and abdominal cavities. The net pressure is the actual effective pressure and is the gross pressure in the structure or organ minus the pressure acting on the outside of that structure or organ. Manometer A records the left ventricular pressure (L V). Manometer B records the net left ventricular pressure (net L V) which is the ventricular pressure minus the thoracic pressure acting on the outside of the ventricle. Increases in the thoracic pressure may increase the left ventricular pressure but it also compresses the coronary vessels. Therefore the thoracic pressure must be subtracted from the systemic arterial pressure in order to evaluate the effective net pressure to the coronaries. This was accomplished by means of the differential manometer B where the left ventricular pressure is led to the back of the manometer and the thoracic pressure is led to the front chamber of the manometer. Manometer D records the right ventricular pressure (R V). Manometer E records the net right ventricular pressure (net R V) this is the right ventricular pressure minus the thoracic pressure acting on the outside of the ventricle. Increases in the thoracic pressure may increase the right ventricular pressure but this is a mere passive rise since it also increases the pressure on the outside of the pulmonary vessels. Therefore the thoracic pressure must be subtracted from the pulmonary arterial pressure in order to evaluate the effective net pressures in the pulmonary circulation. This was accomplished by means of the differential manometer E in a manner similar to that described for manometer B. Manometer C records the net abdominal pressure (net ABD). This is the abdominal pressure minus the thoracic pressure and is the effective net pressure which facilitates or hinders blood flow from the abdominal venous reservoir (inferior vena cava and portal system) to the right side of the heart. Increases in the abdominal pressures effectively increase blood flow to the right heart only when a corresponding rise in thoracic pressure does not occur. The tube T from the balloon in the thorax is also connected to the front chamber of manometer E. See the asterisk (*).

tive-negative intrapulmonic pressures could empty or "milk" enough blood from the capillaries of the lungs to increase the return of blood to the heart effectively.⁶

When cardiac as well as respiratory arrest was produced either with helium or by electrically induced

during "dying gasps," where the effective net left ventricular pressure is sometimes elevated to values as high as 60 mm of mercury.

SUMMARY AND CONCLUSIONS

Seven different forms of mechanical artificial respiration were studied for their influence on the pulmonary and systemic blood pressure. This was made possible by employing a new technic for measuring the effective pulmonary and systemic blood pressure in laboratory animals not operated on and unanesthetized.

Irrespective of the method of mechanical artificial respiration employed, recovery of the animal was accomplished when respiratory arrest and slow weak cardiac contractions were produced with helium. No significant change in pulmonary and systemic blood pressure was produced with any of the methods of resuscitation studied when cardiac and respiratory arrest occurred, either by helium or by electrically induced ventricular fibrillation.

Any blood flow which was produced by the resuscitators did not reach the coronary and cerebral arteries. Instead blood was pushed toward the extremities and cutaneous areas.

Intrapulmonic positive pressure greater than 10 to 12 mm of mercury, if maintained for a prolonged period of time, may hinder venous return to the right side of the heart.

The so-called "milking action" of the intrapulmonic positive-negative type of resuscitator did not effectively increase the return of blood to the heart.

THE RELATION OF ANESTHESIA
TO HYPOXIA AND ANOXIA

RALPH M. WATERS, M.D.

MADISON, WIS.

At the sessions of the Section on Pathology and Physiology in 1940 the word hypoxia was used in a symposium on anoxia to designate milder degrees of deprivation of oxygen. In the present discussion the word hypoxia¹ will be used to mean any reduction in the tension of oxygen which produces disturbances of function only while the reduction persists. Hypoxia has completely reversible effects. Anoxia will mean a reduction of tension of such a degree that it is followed by changes of function persisting after the lowered tension is relieved. Anoxia is characterized by irreversible effects. Admittedly, an immediate decision cannot always be made as to which word, thus defined, ought to be used on a particular occasion. The use of these two terms does, nevertheless, distinguish between a condition of only temporary moment and one causing prolonged inactivity or death of some or all of the cells of the body.

Thus defined, hypoxia, in a majority of cases, is subject to the anesthetist's control. In fact nature, if given a free hand, will often restore the patient to normal. As evidence, we have only to recollect the instances when friendly scuffles, wrestling matches, choking spells and the like have resulted in more or less extreme cyanosis but following which no permanent harm has resulted. Anoxia on the other hand, is an

intolerable condition and, once it is initiated, the effects are not amenable to successful treatment. Anoxia is usually preceded by a period of increasing hypoxia. For this reason the anesthetist must be familiar with the recognition and treatment of hypoxia.

DETERMINATION OF ADVENT OF ANOXIA

The advent of anoxia during a particular anesthetic administration to a particular patient will be determined by (1) the presence and extent of physical abnormalities or disease (2) the presence and extent of reduction in the tension of oxygen to which the tissues are subjected and (3) the duration of exposure to such reduction in tension. As long as anesthetics were administered only to relatively normal subjects for minor operations of short duration, the problem of the transport of oxygen during anesthesia could be left largely to care for itself. As the surgeon has expanded the scope of his endeavor, a greater number of patients are encountered in the highly susceptible groups whose "margin of safety" is subnormal. Many of the commoner causes of inadequate delivery of oxygen to the tissues have been considered in a previous paper² and will not be repeated here. They are obvious to careful diagnostic observation. Forewarned is forearmed. If he realizes the danger, the anesthetist can usually help the patient to overcome defects in transport of oxygen by the selection of appropriate methods and scrupulous application of proper technic. He is less fortunate when he encounters a patient with variations in the supply of blood to an essential region. The size of the arteries and the condition of their walls, the angle at which they branch from larger arteries and the number and distribution of capillaries in a given area may in a particular patient, decrease the amount of blood delivered. Such conditions and the existence of the more obscure biochemical abnormalities in a patient's tissues exaggerate the effect of commoner defects in transport. Prolongation of anesthesia and the exact adjustment of dosage necessary to facilitate delicate and protracted operations increase the possibility of technical error or accident in administration. Physical abnormality and disease predispose the patient to greater damage from these hazards.

Whether anoxic effects are reached in a given patient will then depend on the relative degree of reduction in the tension of oxygen and on the duration of such reduction. The old adage is accurately fulfilled that "what is one man's meat is another man's poison." The terrific strain to which the military aviator subjects himself with safety on some occasions is ample evidence that both the degree and the duration of hypoxia may be considerable in a healthy person without apparent harm. In contrast, one need only gain the confidence of a hostess on a civilian transport plane to learn of the greater severity of symptoms resulting from far lesser decreases in tension in many supposedly normal civilian passengers. The patient handicapped by anatomic abnormality, by illness, by injury or by depressant drugs is merely a person with still less tolerance. Such a person may safely endure a very moderate degree of hypoxia for a considerable period of time or a greater degree for a very short period. The limit is an individual matter. His safety under anesthesia will depend on intelligent supervision, early

recognition of hypoxia, identification of its cause and application—sometimes instantaneous application—of the proper remedy before anoxia occurs

PRACTICAL CONSIDERATIONS

Our search for new drugs has so far failed to find even one which will relieve pain without adding the hazard of hypoxia either by its primary or by its secondary effects. It is true that the manner in which danger threatens varies with different drugs. But whether we administer procaine to make the field of operation insensitve, a derivative of barbituric acid to cause unconsciousness or ether to produce profound anesthesia, the road to disaster passes through hypoxia to anoxia in a majority of cases. The tragic results of total deprivation of oxygen have been appreciated by anesthetists for a great many years. That these effects have been emphasized and elucidated in recent times by the psychiatrist and the pathologist is most fortunate. One wonders however whether an undesirable result may not be creeping into our attitude. Are we "becoming jittery on the subject"? We ought not to fear hypoxia but rather become familiar with it that we may recognize it early and treat it promptly. To the experienced anesthetist hypoxia should be a zone of warning, constituting a margin of safety which must not be exceeded if the patient is to be protected from harm.

How are we to recognize this zone of warning? Physical signs are described in the textbooks and are taught in medical schools. But practical experience is the best instructor. Many older anesthetists of whom I am one, regard the present condemnation of nitrous oxide as deplorable. By its neglect we are depriving our students of the opportunity to become familiar with hypoxia under circumstances which can be made harmless. J. Q. Colton, the lecturer on chemistry who introduced nitrous oxide to Horace Wells utilized and taught a method of administering the pure gas (without oxygen) for the painless extraction of teeth. Literally hundreds of thousands of persons have had minor operations performed painlessly and safely by this method. Those who used it wisely recognized its limitations: physical abnormalities and disease were avoided, the degree of hypoxia was moderate and the duration of administration was brief. Nitrous oxide does not relax skeletal muscles. Attempts to produce this effect have been responsible for its unpopularity. That it is effective for relieving pain in concentrations of 35 per cent and that it produces unconsciousness within ten minutes in concentrations of from 40 to 60 per cent seems to have been overlooked by many.³ To the uninitiated the rapidity of interchange of oxygen and nitrous oxide between the atmosphere inhaled and the tissues of reasonably healthy individuals is unbelievable. With apparatus adequate for the rapid manipulation of these two gases the beginner may be taught the characteristics of varying degrees of hypoxia and the technique of reversing their development at will. The anesthetist who has studied hypoxia under such safe and controlled conditions is in a better position to recognize and treat it early when it is encountered under less favorable circumstances. Let no anesthetist

quote these statements to his surgeon as justification for the prolonged presence of cyanosis. On the other hand it is to be hoped that no surgeon will use them to badger a conscientious anesthetist. A brief period of hypoxia in a healthy patient whether produced inadvertently or for purposes of instruction need not be harmful. A similar period of deprivation may result in anoxia and be fatal to a patient in cardiac decompensation. It ought always to be borne in mind that cyanosis is an unreliable sign. When present, it usually indicates some degree of hypoxia. The absence of cyanosis gives no assurance that the tissues are adequately supplied with oxygen. A pink skin may accompany general hypoxia of biochemical origin or localized hypoxia caused by variations in the supply of blood to a particular region.

USE OF NITROUS OXIDE AND OXYGEN

The medical student and the young anesthetist must learn as much about hypoxia as possible under conditions which are safe for the patient. Such studies can be carried out safely on healthy patients while they are being anesthetized with nitrous oxide-oxygen. The control—the reversal of hypoxic conditions—is sometimes accomplished by increasing the percentage of oxygen in the atmosphere inspired. Oxygen is not however, the only remedy necessary. Early recognition of obstructed, depressed or arrested respiration will require artificial airways, pressure inflation of the lungs or prolonged artificial respiration. The proper training of an anesthetist includes teaching which will familiarize him with all the multitudinous accidents, reflexes and physiologic defects which may be encountered. That these occur but rarely does not excuse us from recognizing them. Only by early recognition of hypoxia can time be gained to restore normal conditions before the zone of warning has been passed. The prompt treatment of mild hypoxia is simple; that of prolonged or severe hypoxia may be difficult but the treatment of anoxia will bring only disappointment.

SUMMARY

The state of anesthesia, however produced predisposes to reduced tension of oxygen.

The word hypoxia has been used in reference to degrees of lowered tension which modify function only while the lower tension persists. The word anoxia has been used in reference to lowered tension of sufficient degree to produce persistent functional disability or death of cells.

The completely reversible nature of hypoxia constitutes a zone of warning which if recognized promptly and treated adequately will serve to protect the patient from anoxia.

The present unpopularity of nitrous oxide-oxygen anesthesia is regrettable. If used intelligently, the rapidity of interchange of these two gases can be utilized to teach the recognition and treatment of hypoxia.

Wisdom seems to dictate to the anesthetist an attitude toward his work which apprehends the imminent possibility of hypoxia at all times. Without this attitude any anesthetic drug administered by any method is dangerous. With this outlook any agent administered by any technique is relatively safe.

PEDIATRIC ASPECTS OF ASPHYXIA NEONATORUM

ALFRED D. BIGGS, M.D.
CHICAGO

When Elisha, the prophet of Ancient Israel, restored the life of a Shunammite woman's boy by blowing his breath into the mouth of the child, he forced oxygen and carbon dioxide into the lungs under pressure. Add to this the obvious expedient of clearing the respiratory passages of the newborn and we have the essence of the modern treatment of asphyxia neonatorum.

A great deal of scientific research and clinical thought has been devoted to this problem during the last ten years, and real progress has been made. This activity has been stimulated by the still appalling death rate among infants¹ during the first twenty-four hours of life and also by the growing conviction that a large portion of mental and motor impairment in later life is due to insufficient oxygenation of the brain immediately after birth.

There is still wide disagreement on every essential involved in this problem, with two exceptions. All are agreed on the advisability of clearing the respiratory passages of debris and keeping the baby warm after delivery. There is disagreement about the use of carbon dioxide, oxygen, drugs of all kinds and cutaneous and other forms of stimulation about artificial respiration in its various forms, about every instrument and machine so far devised and about mouth to mouth insufflation. I have made an extensive appraisal of the literature and will present what appears to be the preponderance of opinion concerning the essential elements of this problem. I have given consideration not only to the number of writers holding a certain notion but also to the extent of the research which backs up that notion and the care with which it was executed. This applies both to scientific and to clinical research. To quote each of these writers individually would obviously be too tedious.

ETIOLOGY

Anatomic Factors—In addition to malformation of the circulatory and respiratory organs, one must think of diaphragmatic hernia, hypoplasia of the mandible² and abnormal mobility of the tongue.³

Obstetric Factors—The preponderance of the opinion of the most careful observers indicates that the incidence and severity of asphyxia neonatorum is directly proportional to the amount of operative work done,⁴ also that it is directly proportional to the amount of anesthesia used in delivery⁵ and to the amount of narcotics given to the mother a short time before delivery.⁷ However, some observers specifically state that both anesthetics and narcotics may be used with discretion at a minimal risk.⁸

Physiopathologic Factors—Most observers agree that prematurity⁹ and intracranial hemorrhage¹⁰ are the two most important single causes of severe asphyxia of the newborn. Other obstetric factors such as prolonged labor and compression of the cord need only to be mentioned.

The term congenital atelectasis is of little value, since it gives no clue to the reason the air sacs fail to function. Is the cause anatomic or physiologic? Obviously damage to the brain stem by hemorrhage or other causes can inhibit the respiratory function. Obviously also prematurity and other debilitating conditions which weaken the muscular power or the general physiologic state are responsible in many cases. But what about the large number of cases of cyanosis in which none of these anatomic, obstetric or specific pathologic states exist?

The great majority of writers follow Henderson's conception that carbon dioxide is the normal physiologic regulator of respiration. However, Eastman has challenged the whole idea when applied to this problem. He argues that the fetus exists normally in a state of cyanosis,¹¹ that there is an excess of carbon dioxide in asphyxia neonatorum which fails to initiate respiration,¹² that asphyxia neonatorum is analogous to experimental asphyxia and that in his experience oxygen is superior to carbon dioxide in initiating respiration in the asphyxiated experimental animal.¹³ A number of writers¹⁴ agree with Eastman. Henderson admits the excess of carbon dioxide in the asphyxiated newborn. He states that in long labor the respiratory center of the brain is dulled by compression and the concomitant reduction of blood supply. Even the increased carbon dioxide of the asphyxiated baby is not sufficient to start respiration.¹⁵ Therefore even greater quantities should be administered therapeutically. Referring to the work of Haldane and his co-workers, Henderson asserts "From their work and those who have confirmed and extended it, it is as certain as anything in the whole range of modern science that respiration is under a chemical control by the more or less direct action of arterial blood, chiefly through its content of carbon dioxide, on the respiratory center of the brain. It has been proved oxygen is not a stimulant."¹⁶ No one can deny that Henderson's point of view is accepted by the great majority of writers.¹⁷ However, it does not necessarily follow that carbon dioxide should be given to an infant whose brain is already overloaded with this gas.

The after-effects of sublethal asphyxia on the central nervous system need more emphasis than they have received. The most highly specialized tissue of the body is the most susceptible to damage from anoxemia. It has been conclusively demonstrated that irreparable damage is inflicted on the nerve cell by relatively short periods of oxygen want. Windle and Becker,¹⁸ by clamping the umbilical cord or the uterine artery for short periods, demonstrated these changes in guinea pigs.

Yant¹⁹ and others have demonstrated that asphyxia results in congestion, in perivascular edema and hemorrhage into nerve tissue and finally in destruction of the neuron.

TREATMENT

The trend of opinion is very definitely away from all types of cutaneous and other peripheral stimulation. Most authors condemn²⁰ severe types of stimulation such as hot and cold baths, spanking, swinging,²¹ dilation of the anus or artificial respiration²² with such adjectives as antiquated, useless, barbaric.²³ However, some still recommend or at least condone²⁴ them.

It is obvious that the air passages should be cleared of debris when it is present and that the baby should be kept warm. Most writers advise removal of debris

Read before the joint meeting of the Section on Nervous and Mental Diseases and the Section on Anesthesiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.
Owing to lack of space the bibliography on pediatric aspects of a phylia neonatorum to which the superior figures in the text refer is omitted in THE JOURNAL but will appear in the reprints.

by suction through a catheter, its introduction being guided by the left index finger in the pharynx.²⁵ Several apparatuses have been devised with side traps to catch the mucus.²⁶

Flagg²⁷ who has given a great deal of attention to this problem, champions the direct laryngoscopic method of clearing the passages, followed by insufflation of the lungs with carbon dioxide and oxygen, if necessary. Many favor Flagg's method.²⁸ In general, obstetricians feel that they have sufficient experience to do the job dexterously without a laryngoscope.

This important question remains. If the infant does not breathe spontaneously, what shall be done to initiate respiration? I shall discuss separately each procedure commonly used.

First. Drugs. The most favored is intracardiac epinephrine.²⁹ There are reports of infants revived by this means after five, ten or twenty minutes have elapsed without any detectable signs of life, during which time all other ordinary methods had failed. Other drugs less frequently advised are posterior pituitary injection,³⁰ alpha-lobeline³¹ and nikethamide.³² These are usually given subcutaneously.

Second. Mouth to mouth insufflation. Opinion is rather evenly divided on the value of this procedure. Many advise it.³³ Some advise against it because of the contamination from the operator's breath.³⁴ Others believe the control of the pressure is not accurate enough and rupture of the alveoli may occur.³⁵ One author advises placing several layers of gauze over the operator's mouth to filter out bacteria. Another devised a special apparatus to meet this problem.³⁶ Others use a catheter in the trachea.³⁷

Third. Drinker type of respirator. Here, again opinion is divided.³⁸ Each side cites clinical and autopsic evidence. In general, opinion seems to be swinging away from the use of this type of apparatus.

Fourth. Other types of respirators. Alternately controlled negative and positive pressure instruments are now favored by many.³⁹ This type of apparatus is similar to that used in giving a closed anesthetic, using a small mask over the baby's face. Thus the gas or mixture of gases can be forced into the nonexpanded lungs by alternating negative and positive pressure. The instrument is adjusted so that the positive pressure does not exceed a specified limit, usually 14 mm of mercury. Some advise a collapsible rubber bag fitted to an infant mask. The gas to be administered is forced into the respiratory passages by manual pressure.⁴⁰ This bag arrangement is simple, inexpensive and easily transported but lacks the automatic control of the respirator. These are the most satisfactory types of apparatus yet devised and are regarded as harmless by most writers. However, some believe they may cause rupture of the alveoli.⁴¹ They do away with the chief objection to the mouth to mouth insufflation, i.e. contamination from the operator's breath.

The principle of rhythmic expansion and collapse of the lungs is based on sound physiology. Sampson Wright⁴² in his *Textbook of Applied Physiology*, quoting Head's experiments, states that if the lungs are forcefully expanded a prolonged expiratory effort is produced, and if the lungs are collapsed a strong inspiratory effort is produced. These results are not obtained after section of the vagus. Other physiologists recognize these reflex actions. Howell⁴³ regards the reflex caused by expansion as the more significant of the two. Corvillo⁴⁴ thoroughly tested the mechanics of

one of these respirators known as the E and J resuscitator. He states that the pressure is constant and that in an opened dog's chest rupture of the alveoli does not occur until the positive pressure exceeds 52 mm of mercury. Birnbaum and his collaborators⁴⁵ have reported resuscitations in advanced experimental asphyxia with a similar positive (14 mm of mercury) and negative pressure (—9 mm of mercury) machine known as the Emerson resuscitator. These animals had ceased to breathe with a rapidly falling blood pressure and would ordinarily have died. Breathing was reestablished in 85 per cent of these animals by forceful rhythmic expansion and contraction of the lungs, although he used an inert gas. He thus demonstrated the aforementioned reflexes.

Considering the problem as a whole it does not make a great deal of difference what method is used to expand the lungs rhythmically. One may use mouth to mouth insufflation or a collapsible bag and mask or a positive and negative pressure respirator to inflate the lungs rhythmically. But if the newborn infant fails to breathe it is mandatory that the lungs be inflated rhythmically by one of these means. The objection that the alveoli may be ruptured has been brought against each of these methods, but this must be put aside in such a grave situation because there appears to be little else of value in initiating respiration after the air passages have been cleared.

Fifth. Oxygen versus carbon dioxide. Whether one uses pure oxygen or 95 per cent oxygen with 5 per cent carbon dioxide is an academic question. A cyanotic baby's brain must be overloaded with carbon dioxide. Why give it more? On the other hand it seems that there can be little difference between the efficacy of 95 per cent and 100 per cent oxygen.

SUMMARY AND CONCLUSIONS

The following outline for the treatment of severe asphyxia of the newborn is dictated by the consensus of the best opinion on this important question.

1. Avoid severe cutaneous or other types of peripheral stimulation, such as hot or cold baths, spanking, swinging and dilation of the anus.

2. Avoid manual types of artificial respiration. Opinion is now also swinging away from the infant Drinker respirator.

3. Keep the baby warm from the moment of birth.

4. Clear the air passages with direct laryngoscopic methods or by suction through a catheter introduced by the sense of touch.

5. If the baby does not breathe spontaneously, oxygen or a mixture of 95 per cent oxygen and 5 per cent carbon dioxide should be rhythmically forced into the cleared passages. This may be done with a controlled alternating positive and negative pressure apparatus or by the use of a rubber bag attached to a mask or by mouth to mouth insufflation or by the operator's breath through a tracheal catheter.

6. It makes little practical difference whether one uses oxygen or a mixture of 95 per cent oxygen and 5 per cent carbon dioxide.

7. One may use drugs such as epinephrine in the heart muscle or alpha-lobeline or nikethamide, subcutaneously, if one is so inclined.

There are some authors who believe that none of these things are effectual in the initiation of respiration. However, few wish to assume such a helpless attitude.

1713 West Ninety-Fifth Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs VOLPITTO, WOODBURY AND ABREU,
DR WATERS AND DR BIGGS

DR HUBERTA M LIVINGSTONE, Chicago As pointed out by Dr Biggs, vigorous methods of resuscitation in the newborn are to be condemned. Nevertheless there should be no delay in rapidly and thoroughly clearing the upper air passages and gently and rhythmically inflating the lungs by mouth to mouth insufflation or the use of oxygen or carbon dioxide-oxygen mixtures. Postnatal oxygen should be used until ventilation is adequate. Dr Waters has clearly emphasized the anesthetist's responsibility for the recognition and treatment of hypoxia or anoxia. This condition may be produced by the improper use of any of our anesthetic agents. Blood arterial oxygen studies have demonstrated that hypoxia or anoxia is not present when nitrous oxide or ethylene is used correctly. The work by Drs Volpitto, Woodbury and Abreu substantiates the finding that prolonged excessive intrapulmonic pressures interfere with cardiac function. We have demonstrated in dogs a lowering of the systemic blood pressure with 10 to 15 mm of mercury of intrabronchial pressure, and right heart failure with higher pressures. Apparatus for delivering oxygen or anesthetic mixtures should be equipped with check valves to prevent increasing intrapulmonic pressures to a dangerous level. Certain methods of anesthesia as well as resuscitation may involve this hazard. The efficiency of various methods of resuscitation is of vital importance. The rocking method recently advocated by Eve deserves further investigation. Anesthetists must appreciate the vital need for the early recognition and treatment of any manifestation of oxygen want. They must also observe the amount of blood loss and see that adequate red blood cell replacement is made to provide not only sufficient circulating blood volume but enough hemoglobin for the transportation of oxygen. Buxton and White have recently reported the unappreciated magnitude of blood loss in even the less extensive surgical procedures. Studies made at the University of Chicago Clinics substantiate these findings, and clinical and experimental evidence emphasizes the importance of adequate whole blood replacement during the period of hemorrhage in order to prevent shock and associated anoxia.

DR W H CASSELS, Chicago The distinction which Dr Waters has made between hypoxia and anoxia is a helpful concept. If we regard hypoxia as the margin of safety between adequate oxygenation and irreversible tissue damage, our attitude toward oxygen want will be much better balanced. It remains of course for each anesthetist to acquire by his own experience and by instruction good clinical judgment as to how wide that margin of safety is in each case. I agree that the anesthetist in training should be given opportunities to familiarize himself with the manifestations of hypoxia. Too many of us, in our fear of any degree of oxygen want have neglected this phase of teaching. Drs Volpitto, Woodbury and Abreu throw valuable light on the dynamics of circulation. The anesthetist becomes familiar with the dynamics of respiration because respiratory activity is easily observed. He is therefore able to deal rationally with respiratory emergencies. If we could acquire equal familiarity with the dynamics of circulation we would be better able to cope with circulatory emergencies. Drs Volpitto, Woodbury and Abreu help us to understand one aspect of this and to evaluate the efficacy of treatment. In fact they have brought out some interesting interrelationships between the dynamics of respiration and circulation. The whole question of resuscitation is too confused in the mind of the average physician. This is because instruction in this matter is too confused or is sadly lacking in many medical schools. The term resuscitation is applied indiscriminately to entirely different methods of treatment for entirely different types of emergencies. Naturally the treatment often does not fit the emergency. If we will differentiate four types of acute emergencies we can resort to appropriate treatment in each case. Respiratory emergencies may involve (1) respiratory obstruction to be treated by relief of the obstruction, (2) respiratory arrest, to be treated by artificial respiration, or (3) a combination of respiratory obstruction and respiratory arrest, to be treated by relief of obstruction followed by artificial respiration.

The fourth emergency is cardiac arrest. This inevitably involves respiratory arrest. Artificial respiration is indicated, but, as Drs Volpitto, Woodbury and Abreu show, it alone is not enough. Steps must be taken to restore circulation. Various steps may be taken of which I will take time to mention but one, rhythmic squeezing of the heart. This has usually been referred to as cardiac massage, but I would suggest that it should be called artificial circulation. If artificial respiration and artificial circulation are maintained, anoxia should be prevented and normal function may be restored.

DR R P MACKAY, Chicago I am interested to hear Dr Waters say something in favor of nitrous oxide anesthesia. I rise to express again doubts that have been expressed by so many before me. He speaks of the usefulness of nitrous oxide in "properly selected cases," but unfortunately he does not give us any detailed information on exactly how to select our cases properly. Presumably we should give particular attention to the cardiovascular efficiency of these individuals. Certainly I believe that nitrous oxide is sufficiently dangerous to warrant particular attention to the heart and circulation before we dare use such an anesthetic. I am particularly concerned over the prevalence of the use of nitrous oxide anesthesia in dentists' offices and other places where minor operations are to be done and where no proper selection of cases can be made. I believe that we must continue to look on nitrous oxide as a dangerous anesthetic.

CAPTAIN W ALLEN CONROY, M C, A U S I am happy to hear the emphasis by Dr Biggs on the dynamic method of resuscitation of the newborn infant. Many of us have emphasized it for a long time. We have had difficulty in putting the idea across with our obstetric colleagues, not because they were against new ideas but because we did not show a sufficient interest in their problem and help them with it. Those who will give a few anesthetics in obstetric cases will soon have an opportunity to demonstrate their methods of resuscitation. A good many times when the obstetrician is going to be busy with the mother he would be glad to have somebody in the room who can take care of the baby. At that time you will have the chance to throw overboard some of the ineffective methods and use a simple method involving the moving of oxygen in and out of the lungs. The infant that may be resuscitated short of what Dr Waters calls anoxia still has some circulation. If we move oxygen into the lungs from our lungs or from the simple bag and mask, that infant will revive. His difficulty is not an obscure one, it is simply that he is anesthetized by non-volatile and volatile drugs and, more important, anesthetized by anoxia. His respiratory center is close to death from lack of oxygen and not from lack of carbon dioxide. His carbon dioxide is probably normal and may be elevated. Regarding Dr Biggs's remarks about the state of the infant in utero, I cannot help but feel that somebody has confused the issue of asphyxia with that of cyanosis. The implication that cyanosis itself is due to carbon dioxide accumulation is false. Many have overlooked that vital distinction. In the matter of recommending what to use for resuscitation, I think we are becoming remiss in even excusing the use of carbon dioxide. We should insist on its abandonment because of the narcotic effect of that substance itself. If we excuse 5 per cent, we shall find 10 per cent, 15 per cent or some unmeasured amount being used as the result of our excusing the smaller amounts.

DR PERRY P VOLPITTO, Augusta, Ga I think it is always worth mentioning at any time when resuscitators are discussed that we should focus our attention always on the principle of avoiding catastrophes—that is avoiding circumstances in which these various types of apparatus might have to be employed. Of course when the occasion comes to use them the proper application of resuscitative equipment is necessary. It is always timely to condemn the placing of mechanical apparatus for resuscitation in the hands of lay persons and medical men not familiar with their use.

DR RALPH M WATERS, Madison Wis I suppose that I was due to have to defend my statement of good will toward nitrous oxide. In obstetric anesthesia I prefer nitrous oxide for release of pain more readily and emphatically than any other agent because of the rapidity with which changes can be made and the baby can be oxygenated in utero or at the end of

delivery I stated that when Dr Colton talked about anesthesia for dental extractions he recommended three things first, that it be used in relatively normal individuals, second that it be used for short periods and, third that it be used with mild hypoxia and never with anoxia. It is true that thousands of patients were anesthetized that way, and safely. We have been making studies in recent years along this line. Dentists have seen long anesthetics administered with other agents and they try to do with nitrous oxide what is done with the other agents. If they would look at the technic used before 1900 they would not have the difficulties we are seeing now. Finally, I want to emphasize another idea. Do not think that oxygen is a sole remedy, that if it is available it will take care of any situation. It will not. It must get into the lungs and into the blood and into the tissues. I have had several experiences that have resulted in brain damage. One was due to electric shock. Before the patient and I had recovered from the electric shock, permanent damage had taken place in the patient's brain. I think we must remember that the anesthetist handling the oxygen must get it where it belongs and must recognize the danger of lack of oxygen. We must retain the term "hypoxia" as a safety ground, not say that we must use no nitrous oxide but rather that we will use nitrous oxide to learn what hypoxia is and thus protect ourselves from injury.

Dr ALFRED D BIRCH Chicago. Just one comment about the defective child having a good memory. A mother is always on the defensive concerning a defective child. She is looking for a redeeming feature. Although the memory is poor, the child does remember certain things. This fact is her main consolation so she dwells on it.

ROLE OF INDUSTRIAL MEDICINE IN THE REHABILITATION OF VETERANS

J F JOHNSON, M.D.

Medical Director, Eastern Aircraft Trenton Division
General Motors Corporation Trenton New Jersey

WITH THE COOPERATION OF

H V HOFFMAN

Employment Interviewer Eastern Aircraft Trenton Division,
General Motors Corporation Trenton New Jersey

TRENTON, N J

The significance of my remarks will be confined to what they actually are, namely, the personal observations of a physician in an industry which is aware of its responsibility to some of these veterans. Table 1 lists the group studied.

One cannot talk about generalities and with these generalities settle any one particular case. The actual disposition and training of "G I Joe" is an individual problem, requiring individual evaluation and individual disposition, it may be incorrect to apply to any 1 case the general opinions gained from studying the group of veterans which we have handled so far. This necessarily individual evaluation is no more true of "G I Joe" than it is of John Doe or Mary Doe the ordinary civilian.

I should like to classify veterans as (1) those who have or have not been former employees and (2) those who have or have not service connected disabilities. I think it is obvious that the primary responsibility of manufacturing industry is to the former employee with a service connected disability.

Tables 2 and 3 show the percentage of workers gainfully employed during peacetime by industry as a whole. Approximately 15 to 24 per cent of gainfully employed persons have worked in manufacturing indus-

try so that this class of industry will be expected to absorb at least 15 to 24 per cent of the returned veterans possibly more.

Another factor that must be considered is that under present seniority rules it is our impression that strictly on the basis of seniority approximately 15 per cent of our former temporary employees-inductees do not have again speaking seniority-wise a right to a job until some 7000 former permanent employees who have longer seniority are placed at work. This is true if our long term seniority employees do not lose their seniority in the meanwhile. I do not wish to attach any more significance to these statements other than to say that these factors must be considered by those boards or committees which are now interviewing soldiers about to be discharged. At present, industry is able to absorb practically all veterans discharged. However there is a problem coming up which some such conference as this may help to solve.

PHYSICAL AND MENTAL CONDITIONS OF VETERANS NOW BEING SEEN

Table 4 lists the type of disability which is present. It will be noticed that the neuropsychiatric group amounts to a large fraction of the whole. It is in this group that problem cases arise. It is not surprising because frequently inability to adapt to army life leads to or brings out the psychoneurotic tendencies of these people. I do not agree with the usual description that they are "simply nervous." If we are to be guided by our experience with the members of this group they are for the most part real psychoneurotic individuals who have sublimated their mental distress into the more material complaint of pain or dysfunction of certain parts of the body. A few case histories later illustrate this point.

The other groups are rather typical of what is found in the civilian population in the realization that at present industry is accepting employees who possibly would not have been accepted during peacetimes.

We find that there is not much difference between the returned veterans as a whole and the civilian group as a whole. The fact that over 25 per cent of this group would not acknowledge their shortcomings is not unusual. It has been our experience that most applicants for a job will not reveal their shortcomings or their defects, because they think such shortcomings will lessen their chance of getting a job, which of course is occasionally true, so it is not surprising that in spite of the fact that each of these veterans has an exit interview during which he is plainly told why he is being discharged, these same individuals were not willing to give promptly the cause for their discharge.

It should be recognized that not all veterans can safely be given a job in the field in which they wish to work. For instance, some with hypertensive or valvular heart disease should not be started on a training program intended to fit them for a laboring job. It is possible that such individuals could be trained to be crib attendants, time clerks or workers at some other nonlaborious type of occupation. We have classified physical conditions into four groups and correlated these groups with job placement possibilities.¹

Table 6 shows how many are restricted in placement. Again the similarity to the civilian group is brought out. The 32 per cent of restricted placement of veterans is somewhat less than the number of civilians who have been restricted in placement because of physical or

Modified presentation at Conference on Convalescence and Rehabilitation New York Academy of Medicine April 26 1944

mental defects That they should be less than the civilian group is not surprising, because this veteran group has been examined and filtered once during the induction examination It is interesting that the monthly turnover is approximately the same as that of the civilian group The type of restrictions placed on

U S E S or some other agency, his record is immediately marked as being that of a veteran he is given a thorough interview, his discharge papers are checked and, following a thorough medical examination and functional classification, depending on his knowledge and experience, he is either placed directly at work or trained either in a formal separate training

school with pay, or, in some instances, trained directly on the job The training period varies according to the individual's dexterity and rapidity of learning As soon as he can be placed confidently in the factory, he is transferred from the training school It might be added that the training facilities used are the same as those available for civilians The only difference so far as veterans are concerned is that whenever these individuals are doing unsatisfactory work they are further and more thoroughly interviewed, and if it is felt that treatment by a physician is necessary they are so advised Occasionally some of these interviews are in effect simply good personnel work in which the individual is advised of his privileges and of his responsibility to the soldiers who are still in service In some instances it can be said that the veteran discharged without a service connected disability has a greater obligation to his buddies still fighting than industry has to him One of our veterans expressed in his own way just such an obligation

It should be kept in mind that our experience with veterans as employees has been mutually satisfactory, and only rarely do we come across a veteran who leans

on his service record and demands a certain job or a certain shift or certain privileges over and above those to which he is fairly entitled

I give a few case histories of individuals who, in my opinion, are veterans only because the preinduction military service examination did not weed them out I mention these cases not because they are typical but because it is just such a case as this that might cause the more deserving veteran some inconvenience (note the need of finding the "real" cause of discharge versus the "alleged" cause)

CASE 1—W T, a man aged 26 in excellent physical condition came to work in October 1943 discharged because of what he stated at that time was asthma He worked satisfactorily for four months and then appeared in the medical department complaining of cramping pains in the abdomen and inability to work He stated that ever since a jeep accident a year before he had had recurring attacks of abdominal pain, some of which were accompanied by vomiting These attacks were terminated abruptly by rest in bed The present attack came on slowly in the past two or three days

Now from this history alone one would expect that this man had had an internal injury due to the jeep accident, but because of the flinching responses of the patient on examination and his failure to localize his cramps in any one particular spot, because repeated examination showed that what area was tender two minutes before was no longer tender, briefly because the examination suggested a psychoneurosis, considerable time was spent digging out the details of the man's life It was found

that at 4 years of age he had swallowed lye, which gave him a stricture of the esophagus, for which he had two abdominal operations. These abdominal operations were completely successful. He had no attacks of cramps until the jeep accident. Extensive x-ray examinations had failed to show any internal injury. Since then, however, worry had brought on the attacks. His present worry is that his common law wife wants him to marry her, and that he does not wish to marry her because of what we shall call incompatibility. He states that he doesn't love her and yet he doesn't have the nerve to tell her so. I think the solution to this problem is obvious, even though court action may result, and during the solution I have no doubt that he will have more abdominal cramps. He returned to work on being reassured.

CASE 2—R E T, a man aged 23, doesn't know why he was discharged on first examination in October 1943 and denied any dizziness or fainting at that examination. Four months later he came into the medical department, complaining of dizziness and shortness of breath and palpitation of the heart when he did heavy work or when bending over or stooping.

Physical examination gave entirely normal results. The following history was obtained. In 1939, 18 tobacco workers and he were in a truck that was struck by a drunken driver, killing a baby who was on the truck and 2 of the veteran's fellow workers and injuring many of his friends. The drunken driver also was killed. Our veteran was thrown, to quote him,

"100 feet," spinning over and over (he became excited during this description), following which he spent ten days in the hospital. Ever since then, whenever he gets into any physical or mental distress, such as embarrassment or fatigue, he has shortness of breath and palpitation.

His service experience was this. On his twenty-fourth day in service he reported sick because of such an attack, and he spent three and one-half months in the service hospital, following which he was discharged. His work was satisfactory while he was working on an assembly job and while he was working as a truck driver, but because he was involved in an accident which was clearly the veteran's fault, he was taken off the truck driving job and moved to a material handling job.

His personal habits were good. He did not drink or smoke, and he attended church regularly. His hobby was billiards, and when I questioned him as to whether he had any dizziness while bending over the billiard table he asserted that he had never had any. I believe this man's attacks are a hangover from the short period of consciousness during which time he was being thrown "spinning" through the air after his automobile accident. He was told that his mind was playing tricks on him, was encouraged about his good physical condition and advised to return to work. He was given some stimulation of a patriotic nature, and he appeared to have benefited greatly from the two hour interview. He has done a satisfactory job since.

CASE 3—R G V P, a man aged 24, was seen in the medical department because he complained that heavy lifting "hurt his stomach." He was discharged from service because of "nervous stomach." After approximately forty-five minutes of talking about this and that he began to get down to business. He stated that while in service and on furlough he married a girl whom he had known for a year and a half. After two days

of married life his furlough was up and he went back to the Army. Five months later, when he came home on furlough, his wife was frigid. On return to service he was seized with pernicious vomiting and symptoms of a "nervous stomach." He received another furlough in four months, during which

time there was an open break with his wife. He threatened to divorce her. On return to service his vomiting increased. Two months later he had another furlough. During this time he learned that his wife was pregnant. She was abusive and profane to him and to her own parents. On return to service he was hospitalized for two months because of continued vomiting which necessitated feeding by vein.

He was discharged from service after recovery and worked in the plant for three weeks. During this time he had sought legal counsel and was advised that he divorce his wife. He was also under the care of his family doctor, but strangely enough he had never told his family doctor of the onset of his

vomiting. To humor the man and as a concession to his being a veteran, he was temporarily restricted from heavy lifting and was advised to avoid the use of intoxicating drinks. He was advised to become interested again in sports or some other hobby and advised to tell his family doctor all about his family troubles. Because he was intelligent, of good physique and good habits, I believe that he is going to make a good employee, once he gets rid of his cause of trouble, namely, his wife.

CASE 4—S G aged 33, came into the medical department complaining that he couldn't stand noise or lifting, that both noise and lifting gave him pains in his arms and around his heart. He was discharged from service because of "flat feet" according to his history.

This man was a "mother's boy" all his life. He was in service a year and a half when he was discharged because of foot trouble, but on further analysis, the following story came out. He was devoted to his mother who died three and a half years ago. He then had a nervous breakdown. Two years ago his fiancée left him because he was too irritable and too jittery so she said. He was unable to adapt himself to army life because any drilling or exercising or any heavy work, gave him pains in the arms and pains around his heart. He had good enough insight to know that there was no reason for him to have pains and yet he insisted that he did have pains. He was thoroughly examined and studied for peripheral vascular disease with completely negative results. He was finally discharged from the Army and since working at the plant he states he has made no friends, he has no hobby, and he just works, eats and sleeps. His lack of mechanical ability discouraged him. Because he had been a supervisor in a welfare agency under the W P A he felt that he was not properly placed. He wanted to do personnel work. He was given rather a long talk in which it was pointed out to him that his W P A welfare work did not fit him for any available jobs here. He was shown that his work was satisfactory to his foreman and he was advised in general to buck up and gain more confidence in himself. This man definitely has an unstable personality which manifested itself in at least two nervous breakdowns even before his mother died. He is going to take considerable nursing, and it is not impossible that he may go downhill and develop a paranoid psychosis unless he learns to occupy his time with more than eating, sleeping and working. I will quote verbatim what this veteran said because it gives an insight into the thoughts of some of these men.

"When I got my discharge papers, I felt glad, but then I felt bad. Then the world was a hazelike before me. I was glad to get out of the Army. I felt like a free man and I didn't feel so good getting out, knowing that I didn't make a good soldier. I didn't know what the civilians would think of me or what the other soldiers would think of me, but you see we're not soldiers, we're civilians but made over into soldiers, but we are not soldiers. We ain't professionals. And then I have been a mother's baby all my life. I didn't feel that I was being a man getting out of the Army. But the Major told me 'Sid, maybe you can do a good job in the war effort. You can't do one here. Go home and do a good job for us out here.' And I knew all the time just as I was talking to the Major, some of my buddies were getting killed."

I cite these 4 cases because if these men were handled in a disinterested way I am sure they would lose their jobs, either because of their professed inability to do their jobs, or because the foreman might have so much difficulty trying to understand them that he might discharge them. Whenever we come across any such personality problem the foreman is advised of the situation and influenced to bear with the shortcomings of the individual during the readjustment period. Occasionally we run across men who are incorrigible and, in extreme cases have had to refer them to the Veterans' Administration hospital facilities or some other appropriate agency.

Another aspect of the subject of veterans in industry is the procedure which we have used in handling veterans who need medical or welfare attention. When an emergency operation is necessary, the nearest Veterans' Administration hospital facility is contacted by phone. That hospital will then take up the disposition of the veteran if the disability is a service connected one. If the disability is non-service connected, the family physician then takes over the care of the nonindigent

person or the local hospital does. If the person is indigent, the local Red Cross chapter takes charge.

In nonemergency situations for service connected disabilities the veteran is referred to the nearest Veterans' Administration hospital. At present, local physicians are being designated as consultants for outpatient examination. For those veterans who are not emergency cases who have non-service connected disabilities, community facilities must be relied on such as the State Rehabilitation Commission of the Department of Labor or a local welfare agency.

I should like to request that the Veterans' Administration issue a directive instructing all factories which employ veterans as to what to do with the various types of cases. In my opinion it is not sufficient to get the information for the veteran. It has been our experience that the veteran does not know where to turn or how to do what he is supposed to do in seeking aid.

SUMMARY

Manufacturing industry in the past has employed only 15 to 24 per cent of all people gainfully employed and most of these employees some 80 per cent of them, worked in factories with less than a total of 500 employees. The average number of employees per factory in the United States is approximately 42 per plant.

I would suggest that the Veterans' Administration set up a local medical or personnel consultant who will act as an adviser to those few veterans who were a community problem before they got into service, were a personality problem in service, and now as a veterans need a guiding hand.

Roughly 85 per cent of veterans working in industry will adjust themselves to their job with no more training or waste motion than industry is now experiencing with its present civilian personnel. I rather feel that training facilities will be available for those veterans, as well as for civilians, and I have no doubt that, as the more seriously injured veterans come back, industry will absorb its share, possibly more in a way that will establish the veteran as a wage earner, in a manner that will instill confidence and respect for himself.

We have had so few really physically disabled individuals that at this writing we cannot evaluate the adequacy of our present training school or methods. I cannot give any experience with totally blind, armless or legless veterans. I believe we must keep in mind that industry is not primarily an occupational therapy institution and that, in order to survive, the training of the more completely disabled veteran must be on a basis that is fair to industry and inspiring to the individual.

CONCLUSIONS

1 Manufacturing industry, especially the small plants, needs a true record of the physical and mental status of returning veterans for proper job placement.

2 In the absence of an intrinsic medical department, some local Veterans' Administration office must function to evaluate physically and mentally the proper placement of the veteran. This agency is urgently needed now.

3 Eighty-five per cent of veterans now returning are satisfactory employees.

4 They differ very little from the civilian worker in industry today.

5 Some veterans need advice in reconstructing their own life. The need for such reconstruction frequently existed before their induction into service.

6 In one manufacturing plant, strictly on a seniority basis 15 per cent of the short term employees who have gone in service will not have a right to a job until some 7,000 other individuals have been placed. Apparently there is a need for appraising the relative value of "seniority" and "being a veteran."

7 Manufacturing industry will probably employ one out of every seven veterans returning, according to our past experience.
